WebGrab+Plus

(WG++)

V1.1.1

Advanced XMLTV EPG Grabber

By Jan van Straaten (jan_van_straaten@outlook.com)

Website: www.webgrabplus.com

(Document revision 10/06/2014, reflects WebGrab+Plus version 1.1.1/54)

Special thanks to Paul Weterings and Francis de Paemeleere

What's in this document:

For everyone new to this program: Read page 3,4,5 and 6 (upto chapter 4.2) and Appendix B

The rest of this document is for everyone willing to develop a SiteIni file or simply wants to know more than the basics.

Even my wife thinks that you are better off studying this manual than watching what is listed on this evenings tv-guide

Table of Content:

WebGrab+Plus , an advanced XMLTV EPG Grabber

1.Introduction

Beside this manual, www.webgrabplus.com/documentation provides additional documentation of various topics not listed here.

1.1 What it does, features

The program grabs EPG data from TV Guide internet sites and

- runs in WINDOWS, LINUX and OSX and

- can grab from multiple sites in one run, programmable by user trough a SiteIni file
- very fast through incremental grabbing (only changed and new shows grabbed)
- programmable through editing commands that enable changing, filtering, adding, moving, removing (parts) and calculating of the xmltv elements.
- regular updates, support, documentation, userguides and a vast collection of SiteIni file available on webgrabplus.com

For a full list of features see APENDIX A

1.2 How to run, files and folders

For WINDOWS, an installation package is provided that creates the default home-folder C:\ProgramData\ServerCare\WebGrab and fills it with all the necessary files and sub-folders. The program can be run by a double click on the also provided icon - or by running the executable which is located in the (x86) C:\ProgramFiles.

LINUX users and users that prefer another home-folder must copy all the required files and folders to it manually. To run the program in this non-standard environment, must be done in command line mode, specifying the path of the home-folder as a command-line parameter. A simple user guide is provided for this situation.

Detailed guide lines for the various types of installation and use of the program are available online in the documentation pages of www.webgrabplus.com

1.3 Xmltv, *Single* - versus *multiple* - value xmltv elements

For an overview of the xmltv elements supported see APPENDIX D, column: xmltv name.

According to the xmltv specification, some elements can have more than one value in the xmltv file. We distinguish *single value* xmltv elements (e.g. description) and *multiple value xmltv* elements (e.g. category, actor). WebGrab+Plus treats them differently. (for examples see 4.2.4 Types)
Note that the element 'title' is a *single value element* but the program supports a second version of the same title (titleoriginal) with different 'lang=' attributes. (See 4.2.5.6 argument *lang)*

2.The grabbing, show update process and update modes:

2.1 The show update process

Assuming a previous xmltv listing exist (e.g. of yesterday), the program reads this and stores it as a target for update and as reference of what shows have to be changed or added. If no xmltv listing exists, the program creates a new one. Before grabbing show details, the program determines if the existing show in the xmltv listing is still valid or needs an update. For that it connects to the TV Guide website and grabs the so called index pages (the html pages that contain an overview the scheduled shows per timespan (e.g. day or several days)). It then compares the shows listed there (channel, start and stop times and title) with shows in the existing xmltv listing. As a result of this comparison the following situations occur:

- same (.), no update .The show in the index page is considered the same as the one in the existing xmltv listing.
- changed (c), update. The index show is different from the xmltv show but they have overlapping or equal time span.
- gab (g), insert . The index show fits in a time gab of the xmltv listing.
- new (n), add . The index show is new, it will be added to the end (or to the beginning if that is the case) of the xmltv listing.
- repair (r), update. This is a special situation that occurs if errors or overlapping shows are detected in the xmltv listing. The program will try to solve this by remove and update.

When the program runs, these resulting situations for each show are printed in the command window like this (the iiii indicates 4 days of index pages downloaded):
iiii.....g.....ccc.....c.c.....g....r.....nnnnnnnnnnnnnnnnnnnnn

The comparison of the show title in the index page (index_title) and the one in the xmltv file is rather complicated and tricky. This is due to the fact that the index_title frequently differs from the one in the show detail page to a certain extend. Differences can be due to abbreviation of long titles, different use of punctuation characters and combination of title with other elements in the index_title (like category and subtitle). The program deals with all those differences through a weighted comparison. The result of this comparison is a 'title match factor', which , roughly, is the biggest percentage of 'matching' words between the two titles in any of the elements of the index_title. If this title match factor is less than the value for it in the SiteIni file (see 4.3) the show is considered - not same - and a show update is started.

For that it will grab the show details from the show detail html page(s) (see 2.3) of the TV Guide website if provided by it.

2.2 The update modes

The program supports a variety of update modes. The preferred and most efficient is 'incremental' (i) Works as described above for all shows in the index page. In this mode the download time is minimized to the minimum.
Other update modes are:

- 'light' (l) which is incremental but forces a re-grab of all shows for 'today' ,
- 'smart' (s) is the same with a forced re-grab for today and tomorrow ,
- 'full' (f) not incremental, forces a full re-grab of all days requested.

Index-only mode:
Besides and independent from the modes mentioned above is a special grabbing mode 'index-only' that is automatically selected by the program if no elements need to be scrubbed from the show detail page. (see also 4.5) This mode is 'superfast' but seldom useful because most sites provide very little show data on the index page. But if you are satisfied with just start and stop times and a title it's there. Occasionally there is a site with richer data on the index page (like tvguide.co.uk). Some sites list only details on the index page or provide only more detailed information for some shows on detail pages. The program automatically recognizes these cases.

2.3 The Grabbed Site pages: Index-page, detail-page and sub-detail-page

As explained in 2.1 , the update process, the program starts with grabbing the index-page to get an overview of the shows for the time period for which epg data is requested. Depending on the update decision outcome and of the availability of them, the program grabs detailed show epg data from the show detail html page. Some sites split the epg data into sub-detail pages. The program supports additional grabbing from one of such sub-detail pages. (see 4.5 and appendix D)

2.4 Robots exclusion standard check

A quote from http://www.robotstxt.org/orig.html to explain:
quote/
WWW Robots (also called wanderers or spiders) are programs that traverse many pages in the World Wide Web by recursively retrieving linked pages. The 'Robots exclusion standard' is a common facility the majority of robot authors offer the WWW community to protect WWW server against unwanted accesses by their robots.
/end quote
Following this definition of WWW Robots, WebGrab+Plus is such a program. Therefore it obeys the methods and rules of this standard in that it displays a warning to the user if a site disallows access to pages that the program wants to grab from.

3. Configuration files

3.1 WebGrab++.config.xml

This file supplies all TV Guide website independent settings for WebGrab+Plus. Among them are - *update mode* - *time span* (the number of days to grab) - and, most important, a *list of channels* to grab. Each channel for which epg data in the xmltv listing is requested needs to be added to this channel list. The channel data in this list consists of the *update* mode (see 2.2) , the *site* to get the data from (see 4) the *site-id* (the channel id of the site, see 4.4.2), the *xmltv_id* (the id by which xmltv recognises the channel) and the channel *display name*.
A typical WebGrab++.config.xml file is listed in APPENDIX B. It also provides the explanation of all the settings. The file is self explanatory. For detailed configuration instructions see *http://www.webgrabplus.com/documentation/configuration*

3.2 MDB.config.xml

The MDB postprocessor of WebGrab+Plus, which is available from Version 1.1.0 onwards, automatically adds movie and serie details from online 'MDB' sites (e.g. IMDb.com) data to the xmltv file created by the basic WebGrab+Plus EPG frontend grabber. It has its own configuration file which resides in the subfolder \mdb of program's home-folder. This mdb.config.xml file also serves as the mdb configuration user guide. An example of it is also listed in APPENDIX B . For detailed configuration instructions see *http://www.webgrabplus.com/documentation/configuration-mdb.*

3.3 REX.config.xml

The purpose of this postprocessor is to re-arrange and edit the xmltv file created by the grabber section of WebGrab+Plus. This can be useful or necessary if the EPG viewer of the PVR/Media-Centre used, or the xmltv importer it uses, does not support all the xmltv elements in the xmltv file created by WG++.

It can:

- Move the content of xmltv elements to other xmltv elements
- Merge the content of several xmltv elements
- Add comments/prefix/postfix text
- Remove or create xmltv elements

E.g.: If the PVR doesn't support import of credit elements (actors, directors etc.) it can add the content of them to the description and remove the original credit elements which are useless. Or, it can move the episode data to the beginning or end of the subtitle element- Etc. ..
It has its own configuration file which resides in the subfolder \rex of program's home-folder. This rex.config.xml file also serves as the rex configuration user guide. An example of it is also listed in APPENDIX B .

4. SiteIni file

For each TV Guide website that is entered in the channel list of the config file (see above) a SiteIni file is required to supply WebGrab+Plus with site dependent settings. The name of this file is directly related to the value of the site attribute in the channel list through the addition of .ini to this value. (e.g. channel list site attribute : tvgids.nl .. SiteIni file name : tvgids.nl.ini)

4.1 SiteIni file Parts

The data in this file consists of the following parts:

- General Site dependent data (see 4.3)
- Data that WebGrab+Plus needs to compose the url's to download pages (see 4.4)
- Data that WebGrab+Plus needs to scrub xmltv elements from the downloaded pages (see 4.5)
- Optional data that allows post modification of the scrubbed xmltv elements (see 4.6)

4.2 The SiteIni file basics

4.2.1 scrubstrings

Most of the settings in this file relate to how WebGrab+Plus extracts ("scrubs") xmltv elements from the TV Guide website html pages. The program supports two methods for that : The 'separator strings method' (described in 4.2.1.1), by means of element separator strings pointing to the start and end of the element to be scrubbed and the 'regular expression method' (described in 4.2.1.2), by which the element to be scrubbed is extracted by means of a 'regular expression'.
Both methods can be used together mixed in one SiteIni file and both cover more or less the same functionality. The 'separator strings method' is the most easy to understand and is recommended if not familiar with 'regular expressions'. The 'regular expression method' can be considered as the 'expert' method and is extremely powerful and compact.

4.2.1.1 The 'separator strings method'

For that it uses (up to) 4 strings that should point to the beginning and the end of the element to scrub. Obvious are the 'element start' es and the 'element end' ee string. They represent the unique strings (e.g. html tags or parts of it) between which required the element is always located on the html page. In most cases such unique es and ee are unavailable because somewhere else in the html page the same strings exist enclosing other data. In that case we need to separate the right es and ee pairs from the unwanted pairs. For that we use the block separators , block start bs and block end be . These should enclose a html region (block) in which es and ee enclose our wanted element and nothing else.

Consider the following sample html:

```
<div id = "detail-page">
  <div id = "program-content">
    <div id = "program-info">
      <img alt="RTL 7" id="channel-logo" src="/media/pc/epg_upc/nl/channel_logos/rtl7.gif" />
      <h3>Basilisk: Serpent King</h3>
      <a class="channel-title" href="/TV/Guide/Channel/RTL+7/Today/">RTL 7</a>
      <div id = "program-desc-text">
        Amerikaanse actiefilm. Een team van archeologen ontwaakt een mythische slang die vernieling zaait. De enige manier om het wezen te stoppen is door een magische scepter te vinden.
      </div>
```

<!-- Genre Subgenre Data -->
<dl>
<dt>Genre:</dt><dd>speelfilm</dd>
<dt>Genre:</dt><dd>sequel</dd>
<dt>Subgenre:</dt><dd>avontuur</dd>
<dt>Duur:</dt><dd>90 min</dd>
<dt>Regie:</dt><dd>Louie Myman</dd>
<dt>Met:</dt><dd>Jeremy London, Wendy Carter, Griff Furst, Cleavant Derricks, Daniel Ponsky, Bashar Rahal</dd>
</dl>

To scrub the title - *Basilisk: Serpent King*- we need es= *<h3>* and ee= *</h3>*. In fact if it is sure that <h3> tag is uniquely used to enclose the title we wouldn't need more than that. However even if that is the case on this (part of) html page, simple html tags like <h3> are seldom unique and thus it is more secure to use the block separators bs= * * and be = *<a class*

It is a little different with the description, here es= * * and ee= * .* Very likely this es is unique for the description, so we wouldn't need block separators.

Strings like bs, es, ee and be will be called scrubstrings in the remainder of this document.

The syntax in which the SiteIni file expects them is :

{type(optional arguments)|bs|optional es|ee|optional be}
or:
{type(optional arguments)|bs|optional es|optional ee|be}

- scrubstrings must be enclosed between curly brackets {}
- the individual entries are separated by a vertical line | character
- the first entry is a type specification, optionally followed by a list of arguments separated by spaces and enclosed between parenthesis (). Explained later in 4.2.4 & 4.2.5.
- !!! notice that es is optional! If es is left blank than bs takes its place!!
- !!! also either ee or be is optional. If be is left blank there is simply no other limit to the block other than end of html page or a next block. Leaving ee blank is a special case, most useful with index_showsplit, see 4.5.1, it will cut the block between bs and be in slices at es. The values of ee and be are allowed to be equal (pointing to the same string). This is sometimes helpful if no be is available following ee . It is advised to specify the value of ee for be , rather than to leave it blank. It results in a more efficient and secure scrubbing.
- !!! every character (with the sole exception of the vertical line |) in the bs, es, ee and be value is valid! Including spaces! So | | specifies a space and is different from || which is empty.
- bs and/or es may be left empty, like ||, in that case the block starts at the beginning of the html page and/or the element starts at the beginning of the block.

To complete a SiteIni scrub specification we need to add the xmltv element name and an action specifier :

ElementName.ActionSpecifier{ScrubString}

The scrub specifications for two scrubstrings from above for description and title respectively:

```
description.scrub {single|<div id = "program-desc-text">||</div}
title.scrub {single|<div id = "program-info">|<h3>|</h3>|<a class}
```

4.2.1.2 The 'regular expression method'

Most of the functionality to extract selected EPG data from the pages received from the TV Guide sites is covered by the 'separator string' method described in the previous chapter. Besides that the program offers the 'regex' method.
This method is very powerful and flexible but requires detailed understanding of the Regular Expression syntax. Therefore it is only recommended for experienced SiteIni designers with this knowledge or the determination to delve into it.

As introduction a quote from Wikipedia, http://en.wikipedia.org/wiki/Regular_expression :

quote/
..... a regular expression (abbreviated regex or regexp) is a sequence of characters that forms a search pattern, mainly

for use in pattern matching with strings, or string matching, i.e. "find and replace"-like operations. ....
/end quote

The program supports the use of these 'regex' as an alternative for the *'separator strings method'* described in 4.2.1.1

More information about regular expressions in general, besides the Wikipedia article, can be found in http://www.regular-expressions.info/tutorial.html and numerous other articles in the www domain.
The program uses the .NET regular expressions library as documented in http://msdn.microsoft.com/en-us/library/hs600312.aspx

The detailed description of the syntax and use of this extraction method is found in chapter 4.2.4.3, type 'regex'.

4.2.2 ElementNames :

In this document an *element* is defined as a named string object or an array of them in which the result of an action (scrub, modify etc. see 4.2.3) is stored. Their name consists of a fixed part (see Appendix D, first column) that describes the type of data it contains — and, in most cases, a prefix that indicates from which of the html pages (see 2.3) its data is obtained.

A complete list of supported elements can be found in APPENDIX D, first column SiteIni name.

Elements with a prefix index_ are scrubbed from the index page, the ones with prefix detail_ or without a prefix from the show detail page and the ones with prefix subdetail_ from the sub-detail page. Notice that most elements can be scrubbed from either of the three possible html pages. This depends on the actual content of these pages. It is allowed to have an element scrubbed from more than one page, in that case the scrubbed values will be added in a way which depends on if it is a *multiple value* xmltv element or not. (see 1.3 and 4.2.4). In the case of a *multiple value element* they will be listed as separate elements, while when it concerns a *single value element* the values are merged. (for more explanation see 4.6.2.1)

The obligatory elements (un-checked *optional* column in Appendix D) are either required for proper functioning of the program (url_index and urldate to connect to the site, index_showsplit to separate the show index parts, index_start and index_title for update decision making) or as a minimum for a meaningful xmltv output (index_start and title or index_title).

4.2.3 Action specifiers :

Action specifiers are either *url (optional), headers, format , scrub* or *modify.* They specify what kind of action the program has to perform. See APPENDIX D for an overview.

4.2.4 Types :

Type is *url, single*, *multi* or *regex*

4.2.4.1 type *url* :

Scrubstring specifications for this type have varying formats to build the url's to connect to the various site pages. (see 4.4)

4.2.4.2 types *single* and *multi* :

Very often elements in html pages are divided in several paragraphs or otherwise split into parts such that no *single* pair of element separators (es and ee) enclose the element.
Suppose the description in the html page looks like this:

```
<div id = "program-desc-text">
  <p>Amerikaanse actiefilm.</p>
  <p>Een team van archeologen ontwaakt een mythische slang die vernieling zaait. De enige manier om het wezen te stoppen is door een magische scepter te vinden.</p>
  <p>Geproduceerd in 1998</p>
</div>
```

In such a case we use type *multi* to instruct WebGrab+Plus to scrub all the elements within the block with the specified element separators, like here es = and ee =

To illustrate the scrub results from this html with type *single*:

description.scrub {single| | | |</div} will result in :
`<desc lang="xx">Amerikaanse actiefilm.</desc>`

While the same with type *multi* :

description.scrub {multi| | | |</div} will result in :

<desc lang="xx">Amerikaanse actiefilm. Een team van archeologen ontwaakt een mythische slang die vernieling zaait. De enige manier om het wezen te stoppen is door een magische scepter te vinden. Geproduceerd in 1998</desc>

Notice that WebGrab+Plus adds the three description paragraphs together. This is due to the fact that the element description is a *single value* xmltv element. (see 1 and 4.2.2)
To illustrate what happens with a *multiple value* xmltv elements, consider the category.
In the html the genre and subgenre are the obvious choice for that. Xmltv doesn't specify a subgenre element, so we take them all together as category

```
<!-- Genre Subgenre Data -->
<dl>
<dt>Genre:</dt><dd>speelfilm</dd>
<dt>Genre:</dt><dd>sequel</dd>
<dt>Subgenre:</dt><dd>avontuur</dd>
<dt>Duur:</dt><dd>90 min</dd> </dl>
```

There are two genre entries in the html, with the same element separators, so we use type *multi* to grab them both.
category.scrub {multi|<!-- Genre Subgenre Data -->|<dt>Genre:</dt><dd>|</dd>|</dl>}
The result will be the following xmltv listing for category:

<category lang="xx">speelfilm</category>
<category lang="xx">sequel</category>

Because category is a *multiple value xmltv* element the two are not joined to one xmltv element but listed as separate category elements.

To add the third category element , the Subgenre in the html, we use another feature of the SiteIni specification : For most SiteIni elements it is allowed to use more than just one scrub specification for the same xmltv element! (see APPENDIX D column - multiple scrub- which)
So we add:
category.scrub {single|<!-- Genre Subgenre Data -->|<dt>Subgenre:</dt><dd>|</dd>|</dl>}

The final result:

<category lang="xx">speelfilm</category>
<category lang="xx">sequel</category>
<category lang="xx">avontuur</category>

4.2.4.2 type *regex* :

Used to specify the 'regex' method of data extraction. See also 4.2.1.2 for some background information. This method doesn't need the type *single* and *multi* distinction as is explained below.

The syntax:

Element.scrub {regex(optional argument)||regular expression||}

- *regex* : the action specifier for this method
- *argument* : for this method the only argument supported is *debug* (see arguments 4.2.5.5)
- *regular expression*: The regular expression that matches the desired element content.
- The place of the regular expression in the scrubstring is the same as the 'element start - es' in the separator string method (see 4.2.1.1, syntax) or, simply put, two || in front and two || after it.

The easiest way to get started with this method (after mastering the 'separator string' method) is to use a direct substitution of the separator strings be, es, ee and be used there.
Remember the syntax for the separator string method (see 4.2.4.2 type *single* and *multi* explanation)For type *single*:

Element.scrub {single(arguments)|bs|es|ee|be}

A direct 'regex' substitute for it will be:

Element.scrub {regex(arguments)||bs(?:.*)es(.*?)ee(?:.*?)be||}

Examples: The 'separator string method' title solution of the previous chapter:
title.scrub {single| |<h3>|</h3>|<a class}

can also be achieved with the following regex scrubstring:
title.scrub {regex|| (?:.*)<h3>(.*?)</h3>(?:.*?)<a class||}

And for the description :
description.scrub {single| || }
description.scrub {regex|| (.*?) ||}

For type *multi* the substitution is as follows:

Element.scrub {multi(arguments)|bs|es|ee|be}

Will look like this in regex:

Element.scrub {regex(arguments)||bs(?:.*)(?:es(.*?)ee(?:.*?))*be||}

Example the category of chapter 4.2.4.2

category.scrub {multi|<!-- Genre Subgenre Data -->|<dt>Genre:</dt><dd>|</dd>|</dl>}
category.scrub {regex||<!-- Genre Subgenre Data -->(?:.*?)(?:<dt>Genre:</dt><dd>(.*?)</dd>(?:.*?))*</dl>||}

4.2.5 Arguments:

Arguments can be either/and *includeblock, excludeblock, separator, max, include, exclude, debug* and dedicated arguments *lang, force, sort, timespan, preload, alloc, target.*

!! All these arguments are irrelevant for type *regex*, with the exception of *debug* !

4.2.5.1 Argument *includeblock* and *excludeblock* :

If it is only possible to find blocks that, apart from the required information, contain unwanted information with the same element separators *es* and ee , these arguments can be used to select the correct blocks. The syntax:

includeblock=bn1,bn2, .. ,bnn/tn -or- "string-1""string-2" .. "string-n"
excludeblock=bn1,bn2, .. ,bnn/tn -or- "string-1""string-2" .. "string-n"

- *bn* , the block number to include or exclude, starting with 1
- *tn* , the number of blocks for which the block numbers bn repeat
- "*string*" , include or exclude only the blocks that contain the "string". When more than one "string" is entered, the block selection is done by an 'or' function of the strings. The use of wildcards [x] and [?] is allowed (see 4.2.6)
  Example : includeblock="abc""def" , the blocks included contain the string "abc" or "def" .
  When more than one "string" is entered separated by the char & , the block selection is done by an 'and' function.
  Example : includeblock="abc"&"def" , the blocks included contain the string "abc" and "def".
- All characters are allowed.
- The characters " ' { and) need to be preceded by \ . So the string ("O'Neil {superhero}") must be entered as "\(\"O\'Neil \{superhero}\"\)"

4.2.5.2 Argument *separator* :

As example take a look at the actors :
<dt>Regie:</dt><dd>Louie Myman</dd>
<dt>Met:</dt><dd>Jeremy London, Wendy Carter, Griff Furst, Cleavant Derricks, Daniel Ponsky, Bashar Rahal</dd>
</dl>

If we use : actor.scrub {single|<dt>Met:</dt>|<dd>|</dd>|</dl>} the xmltv listing of actor will be
<actor>Jeremy London, Wendy Carter, Griff Furst, Cleavant Derricks, Daniel Ponsky, Bashar Rahal</actor>

That is clearly not what we want. To separate them we use the *separator* argument. It specifies which string or strings separates the elements. Its syntax is:

separator="string-1" "string-2" .. "string-n"

- Between the separator strings a space is allowed but not required.
- All characters are allowed with the exception of | (vertical line). This is no limitation of this function because the program will automatically replace all | characters in the html page into the character combination !?!?!, this to avoid

problems with the special function of this character.
- The characters " ' { and) need to be preceeded by \ So the string ("O'Neil") must be entered as separator="\(\"O\'Neil\")"

The scrub specification for actor then becomes:
actor.scrub {single(separator=", ")|<dt>Met:</dt>|<dd>|</dd>|</dl>} and the resulting xmltv listing:

```
<actor>Jeremy London</actor>
<actor>Wendy Carter</actor>
<actor>Griff Furst</actor>
<actor>Cleavant Derricks</actor>
<actor>Daniel Ponsky</actor>
<actor>Bashar Rahal</actor>
```

Suppose the html line with the actors looked like this:
<dt>Met:</dt><dd>Jeremy London, Wendy Carter, Griff Furst, Cleavant Derricks, Daniel Ponsky and Bashar Rahal</dd>
(The last two actors separated by the word - and -) We then can use separator=", " " and " for the same result.

4.2.5.3 Argument *max* :

To limit the number of elements (either added together in the case of *single value* xmltv elements or listed separately in the case of *multiple value* xmltv elements) we can use the argument max. Its syntax:

max=n in which n=positive integer

actor.scrub {single(separator=", " max=3)|<dt>Met:</dt>|<dd>|</dd>|</dl>} will result in:

```
<actor>Jeremy London</actor>
<actor>Wendy Carter</actor>
<actor>Griff Furst</actor>
```

4.2.5.4 Arguments include and exclude :

These allow further control over which of the scrubbed elements will be passed to the final result. It is important to realise that both *include* and *exclude* can be used together in one scrub specification. The program will execute these in the order in which they occur in this specification. See for an example of the effect of this in 5.
Its syntax:

include=n -or- first -or- firstn -or- last -or- lastn -or- "string"
exclude=n -or- first -or- firstn -or- last -or- lastn -or- "string"

- *n* the element number to include or exclude, starting with 1
- *first* or *firstn* (like first2) , the first or the first n elements to include or exclude
- *last* or *lastn* (like last2) , the last or the last n elements to include or exclude
- "*string*" , like "met o.m.", include or exclude only elements containing the "string". The use of wildcards [x] and [?] (see 4.2.6) is supported.
- All characters are allowed with the exception of | (vertical line). This is no limitation of this function because the program will automatically replace all | characters in the html page into the character combination !?!?! , this to avoid problems with the special function of this character.
- The characters " ' { and) need to be preceded by \ So the string ("O'Neil") must be entered as "\(\"O\'Neil\")"
- As with the argument *separator* (see 4.2.5.2) a list of strings is allowed like:

include="string-1" "string-2" .. "string-n"

The effect of these arguments differs depending on whether it is entered in - combination and after the argument *separator* — (case A) or not (case B).

Case A (after the argument *separator) :*

In this case it allows to make a selection of the elements we want after they are separated.

As example we use the following html for a title and sub-title combination that occurs frequently:

```
<div class="intro-datasheet">
  <div class="img">
    <img src="/img/programas/fotos/Motociclismo255.jpg"  alt="" />
```

```
    <p>Motociclismo: Cto. del Mundo</p>
  </div>
```

Here, the title *Motociclismo,* is separated from the sub-title *Cto. del Mundo* with a : character.
So we can use the arguments *separator=": "* to separate them , we then use *include=first* for the title and *exclude=first* for the sub-title, like this:

```
title.scrub {single(separator=": " include=first)|<div class="intro-datasheet">|<p>|</p>|</div>}
subtitle.scrub {single(separator=": " exclude=first)|<div class="intro-datasheet">|<p>|</p>|</div>}
```

The xmltv result :

```
<title lang="es">Motociclismo</title>
<sub-title lang="es">Cto. del Mundo</sub-title>
```

Case B (not after the argument *separator*):

The program will evaluate all the scrubbed elements (single or multi) on the conditions specified by the include and/or exclude values.
As example we use the description again:

```
<div id = "program-desc-text">
  <p>Amerikaanse actiefilm.</p>
  <p>Een team van archeologen ontwaakt een mythische slang die vernieling zaait. De enige manier om het wezen te stoppen is door een magische scepter te vinden.</p>
  <p>Geproduceerd in 1998</p>
</div>
```

Remember the original scrub specification:
`description.scrub {multi|<div id = "program-desc-text">|<p>|</p>|</div}` resulted in :

```
<desc lang="xx">Amerikaanse actiefilm. Een team van archeologen ontwaakt een mythische slang die vernieling zaait. De enige manier om het wezen te stoppen is door een magische scepter te vinden. Geproduceerd in 1998</desc>
```

But, the last element - Geproduceerd in 1998 — actually belongs to another xmltv element — date – which is meant to contain the date of production. So in fact it shouldn't be part of the description. We can use the following to exclude it from the description:

```
description.scrub {multi(exclude="Geproduceerd")|<div id = "program-desc-text">|<p>|</p>|</div}
```

or if we are sure that it is always the last element that contains the production date:

```
description.scrub {multi(exclude=last)|<div id = "program-desc-text">|<p>|</p>|</div}
```

or if it is always the third:

```
description.scrub {multi(exclude=3)|<div id = "program-desc-text">|<p>|</p>|</div}
```

or

```
description.scrub {multi(include=first2)|<div id = "program-desc-text">|<p>|</p>|</div}
```

Even this works!
`productiondate.scrub {multi(include="Geproduceerd")|<div id = "program-desc-text">|<p>|</p>|</div}` or
`productiondate.scrub {single|<div id = "program-desc-text">|Geproduceerd|</p>|</div}` both will result in:

```
<date>1998</date>
```

(this works because WebGrab+Plus finds any year value inside an element for the date xmltv element, see 4.5.2)

4.2.5.5 Argument *debug* :

Adding the word *debug* as argument will start logging of the scrubbing process for the element in the *WebGrab++.log.txt* file. The html page from which the scrubbing is attempted is written to a separate file *html.source.htm* One should use this argument (preferably) for one element and one show at the time, otherwise the results could be confusing. The config file allows to Grab only one show with the -timespan- setting. Another way to reduce the debug logging to one show is to add an index number *n*, like *debug.4* , in this way only the 4th show from the index page will be logged.

4.2.5.6 Dedicated Arguments:

The following arguments are dedicated to the use with a certain element

- *lang :* This argument only works for the element *titleoriginal*. See 4.5.2, titleoriginal.
- *force :* This is a special argument to change the effect of scrubbing the element *index_date* (see 4.5.2)
- *sort* and *timespan* : Arguments to be used together with *index_showsplit* in case of fragmented multiday indexpages (see 4.5.1)
- *preload* : Used together with any of the 3 url elements (see APPENDIX D and 4.4) Can be used to specify an url that is preloaded before the actual url that calls the requested html page.
- *alloc* : Can be used in the special elements *index_site_id* and *index_site_channel* to specify the target xmltv elements. See 4.5.3
- *target* : Must be used together with the special element *sort_by* which holds the data by which a *target* multi value element will be sorted with the command sort (see 4.5.3 and 4.6.4.9)

4.2.6 String matching / wildcards

The arguments *includeblock, excludeblock, include* and *exclude* , as described in 4.2.5 one can use strings to match with data in the elements. Normally the program uses a one-to-one-case-sensitive match. It is possible however to use 'wildcards' in the strings to match. Wildcard syntax :

[x] represents a multiple character wildcard
[?] represents a single character wildcard

Examples:

- "a[*]c" matches with "abc" and "avdgec" etc.
- "a[?]c" matches with "abc" and "ahc" etc.

Wildcards can also be used in conditional arguments (see 4.6.2)

4.2.7 TimeZones

(see also article http://www.webgrabplus.com/content/times-time-zones-and-dst-corrections)

For the calculation of the xmltv start and stop times, the program needs the time zone and the daylight-saving-time (dst) rules applicable for that time zone. This must be entered by means of a timezone_id in the *time zone* parameter of the General Site dependent data (see 4.3, time zone). The syntax :

timezone=timezone_id

- timezone_id, e.g *US/Eastern* or *Europe/Brussels* or *Asia/Singapore* or *UTC-05:00* or *UTC*
  The program contains an integrated time zones database of more than 400 of such timezone_id's together with their dst rules which is based on *tzdata* as distributed by http://www.iana.org/time-zones.
  Entering *timezone=?* will list all the available timezone_id's together with their basic utc offset in the logfile. This to facilitate the choice. As the examples illustrate, it is also possible to enter just the UTC offset, like UTC-05:00, the program will map this offset to the most likely timezone_id. Just entering UTC without the offset is a special case to be used if the guide times are listed in UTC , without dst rules. (this is not the same as UTC+00:00 !!)
- For the processing of the time zone database the program uses a customized version of the public domain ZoneInfo Api developed by Mark Rodrigues as published @
  http://www.codeproject.com/Articles/25001/ZoneInfo-tz-Database-Olson-Database-NET-API.
- Timezones database updates : As this database is integrated into the program, updates, if necessary, will be provided by a program update published on www.webgrabplus.com. It is also possible to place an updated version of this database in the same folder as the executable *WebGrab+Plus.exe.*
  The program accepts two variants of this database, as *TimezonesData.txt,* a single file variant provided by the www.webgrabplus.com in the download section —or– as a folder *tzdata* as provided by http://www.iana.org/time-zones.
  In both cases the program will use the external database instead of the integrated one.

4.3 General Site dependent data:

One or more lines with the following syntax:

site {url=x.x|timezone=UTC+nn:00|maxdays=n.p|cultureinfo=xx-XX|
charset=xxx,yyy|titlematchfactor=nn}

and the following (and more) are optional:

site {ratingsystem=xxx|episodesystem=xxx|grabengine=wget| firstshow=n|firstday=nnnnnnn|subtitlestype=xxx|retry=xxx}

- Site dependent data can be entered on one or more lines starting with the word 'site'
- *url*, e.g. url=tvgids.nl , the url of the site e.g. url=tvgids.nl
- *timezone*, e.g. US/Eastern or UTC+01:00, the timezone for which the TV guide data is given. See 4.2.7 for details.
- *maxdays*, specifies the number of days n for which TV guide data is provided by the site, followed by how many index pages p are used for it. If n and p are equal, e.g. 7 days on 7 pages, you can either specify 7.7 or just 7. However if the site has a multiday e.g. a weekly indexpage 7.1 must be specified. (See also 4.5.1, index_showsplit)
- *cultureinfo*, e.g. cultureinfo=nl-NL , gives data about standards for time and language formats used by the site. For more info : <http://msdn.microsoft.com/en-us/library/system.globalization.cultureinfo(v=VS.95).aspx>
  It is allowed to only specify the language part of it, like cultereinfo=en , but the results might be different, especially in country specific items like time formats.
- *charset*, e.g. charset=ISO-8859-1 or UTF-8. Charset is normally found somewhere at the beginning of the grabbed site page. Sets proper decoding of these pages. This charset is applied to all grabbed html pages (index, show-detail and sub-detail). Sometimes the charset for these pages is different. In that case specify them separately, separated by a comma. The first will be used for the index page the second for the show-detail and the sub-detail page.
- *titlematchfactor*, e.g. titlematchfactor=50 , this is a number from 0 to 100 that specifies how strict the title comparison is done by WebGrab+Plus (as discussed in 2.1). Some sites use different show titles for the index pages and show detail page. Start with a high value e.g. 90 and adjust to lower if too many unnecessary show updates occur. (see also 4.5.1 element index_title)
- *ratingsystem* (optional) Specifies the system attribute of the xmltv element rating. Some countries have a uniform system to classify shows (e.g. the MPAA in the US and KIJKWIJZER in the Netherlands). If the site's country has no such system it is best to use a two letter country spec like ES for Spain.
- *episodesystem* (optional), specifies the xml attribute system of the episode-num xmltv element. See xmltv specification for details. The most common values are *xmltv_ns* and *onscreen.*
- *grabengine* (optional), specifies which of the two available grabengines (the part of the program that connects to the site and grabs the html pages) will be used for this site. Any other value than 'wget' will use the standard internal .net based grabengine. The other one is the external 'WGet.exe', some sites might behave better with it.
- *firstshow* (optional). Specifies which is the first show on the indexpage that will be processed (scrubbed). When not specified, or if firstshow=0, it starts with the first show found on the indexpage. This value is important for sites that lists shows on the indexpage from the previous day 'yesterday', because the program assumes that the first show is of 'today'. A mix-up of the date value will be the result. The firstshow value allows to skip these 'yesterdays' shows. Instead of a number, the string *now* can be used. This will skip all shows until a day change (passing midnight) is detected.
- *firstday* (optional), e.g. firstday=0123456 This is to be used if the site has a multiday index page (an overview of shows for several days). When in such a case, this indexpage doesn't change for several days (remains starting on the same day), the program needs info where to start. The firstday value tells the program how many days to skip to find the shows of 'today'. It needs to be entered as 7 numbers, from the first : days to skip on Monday .. To the last : days to skip on Sunday.
  Suppose a multiday indexpage which lists the shows for a week starting Sunday. Then if we grab on Sunday there is no need to skip a day, but on Monday we must skip 1 day (the Sunday), on Tuesday we must skip 2 days ... Etc. We specify firstday=1234560
- *subtitlestype* (optional). Specifies the xmltv attribute type of the element subtitles. Possible standard values are *teletext, onscreen* and *deaf-signed.*
- *retry* (optional). This is the same retry setting as the general retry setting in the config file (see 3 and APPENDIX B). If a site is markedly slower than others used in the same run, it is possible to set different retry, timeout and delay values for that site here. The syntax is the same as in the config file. E.g. retry=<retry>12</retry> or
  retry=<retry time-out="10" channel-delay="5" index-delay="1" show-delay="1">4</retry>
- *keeptabs* (optional) This will disable the default replacement of tab \t characters in spaces in html pages. In some cases tabs can be useful in scrubstrings.
- *keepindexpage* (optional) Saves the index-page for use with other channels of the same site. Useful when a site list all or a group of channels on one index-page. It saves grabbing the same index-page again and again.
- *loadcookie* (optional) If a site requires a login with username and stores your personal settings in a cookie, it is necessary to load this cookie into WG++ for it to send to this site as part of the WebRequest. Specified as *loadcookie=cookie-file-name.* The

cookie-file-name is the name of the cookie file which must be present in the WebGrab home folder. (see loadcookie.txt on the download page for how to create such a file , http://www.webgrabplus.com/sites/default/files/download/documentation/Set%20of%20help%20files/help-files.zip). The program filters the cookies in this cookie-file for the cookies relevant for the site, using the url (see above) as domain. Optionally the *cookie-file-name* can be followed by additional domain strings that specify which of the cookies for other domains will be kept. Example : site{loadcookie=yourtv.com.au.cookie.txt} or site {loadcookie=yourtv.com.au.cookie.txt,yahoo.com}

- *skip* (optional) Can be added if a site needs a different (than the one in the config file) setting for any of the values of skip. It overrules the config setting. It must be specified using the same syntax as required for the config file.
  E.g. skip=<skip>16,1</skip>
- compression (optional) The program is able to decompress compressed site responses. Specifying a value for compression like *gzip* or *deflate* will invite the site (by means of the httpwebrequest header *Accept-Encoding*) to use compression. If a compressed response is the result, the program will automatically enable decompression. If no value is entered for compression the header Accept-Encoding will not be issued.
- nopageoverlaps (optional) If subsequent index pages have no overlapping index shows, this setting can be used to disable the automatic removal of these duplicates. This automatic removal can cause problems when channels have few shows per day and/or long gabs in the programming.
- allowlastpageoverflow (optional) When the last shows on the index page are in fact shows from the following day, specifying this will grab these shows even when outside the range of the <timespan> setting in the config file.

Example:

site {url=tvgids.nl|timezone=UTC+01:00|maxdays=6|cultureinfo=nl-NL|charset=ISO-8859-1,UTF-8|titlematchfactor=90|firstshow=5}
site {ratingsystem=KIJKWIJZER|episodesystem=xmltv-ns|grabengine=standard|retry=<retry time-out="15">10</retry>|keeptabs}
site {keepindexpage|loadcookie=yelo.be.cookies,yahoo.com|skip=<skip>noskip</skip>|compression=gzip|nopageoverlaps}

4.4 Data that WebGrab+Plus needs to compose the url's to download pages

4.4.1 General URL settings

The majority of the TV Guide websites use the HTTP or HTTPS protocol. The following chapters describe the setup for this protocol. Beside that the program supports the FTP and the File protocol. These are described briefly in 4.4.4

4.4.1.1 HTTP Headers, method GET, POST, POST-BACK and SOAP

The program supports the following HttpWebRequest methods:

- Method GET: The default way (method) to get a response from a site for a specific html page is to do a 'GET' HttpWebRequest for the url of that page. The URL contains all the necessary details to specify the requested content, usually in the form of a *channel* and a *date* variable.
- Method POST (see 5.1.1 for more details): A common alternative way (method) is to do a 'POST' HttpWebRequest to a specific url which is accompanied by a header 'postdata' with a string which further specifies the request.
- Method POST-BACK (see 5.1.2 for more details): This is a rare variant of the POST method. It starts with a GET request on which the site responds with a html page containing the 'postdata' , most of it, but not all, in a variable named *VIEWSTATE*. All the following requests are to be done with method POST using the 'postdata' as received from the site.
- Method SOAP (Simple Object Access Protocol) (see 5.1.3 for more details): Another rare variant of the POST method. In this variant the details of the request are not send to the site by means of the 'postdata' header but by means of an xml file containing the *soapEnvelope.*

To specify which of these methods is to be used the action specifier *headers* must be used. Besides *method* a number of other headers can be set in this manner.
The syntax:

urlname.headers {headername=string|...|headername=string}

- urlname : either *url_index*, *index_urlshow* or *index_urlsubdetail*
- headername : The following headernames are recognized by the program:
  - *method=GET* (default), *method=POST, method=POST_BACK and method=SOAP*
  - *contenttype=application/x-www-form-urlencoded* (default)
  - *referer=string* (optional)

- *accept=string* (optional)
- *credentials=name,password* or *name,password,domain*
  (optional, for sites that require the approved identity of the user)
- *allowautoredirect=boolean* (optional) Values : *true* or *false,* default true
- *expect=string* (optional)
  Values : *100-continue=false* or *100-continue=true* or *100-continue* (same as =true)
- *host=string* (optional), to overrule the default host header that equals the url of the request

Most other headers that might be required can be constructed with a 'customheader':

- *customheader=headername=headervalue*
  e.g. customheader=Accept-Encoding=gzip,deflate

And, only of significance for *method= POST, POST_BACK* or *SOAP :*

- *postdata=post-data-string*
  This header which is, by its definition, only meant to contain the postdata string for a regular POST method, like POST and POST_BACK. The program also uses its value for the SOAP method to fill the soapEnvelope xml file (see 5.1.3)
  - *post-data-string* : this string may contain the following variable components:
    in a *postdata* header for url_index:
    - 'urldate' to specify a date/time component (see 4.4.2.1)
    - 'channel' to pass the site_id of the channel
    - 'index_variable_element' (see 4.5.3, special elements)
    - 'subpage' to pass the subpage data (see 4.2.2.2)

    in a *postdata* header for index_urlshow or index_urlsubdetail:
    - 'index_variable_element' (see 4.5.3, special elements)

All headers may also contain the element values: 'index_temp_1 to _6' .They will be expanded to their content value similar to other variable components.

Example:
url_index.headers {method=POST|contenttype=application/x-www-form-urlencoded}
url_index.headers {postdata=getEPG&StartTime='urldate'&ChannelIDs='channel'}

4.4.1.2 argument preload

Some sites require a call to a specific url prior to the one with the required data. The program saves the cookies from the response of this preload and re-issues it in the following httpwebrequest. Such a preload can be done by adding the argument *preload.* Example:
url_index {url(preload="http://www.mobistar.tv/tv-guide.aspx")|http://www.mobistar.tv/epg.aspx?f_format=pgn&medium=0&lng=nl&f=|urldate|&t=xxxxx&s=|channel|,0,2,&_=|urldate|}

4.4.2 url_index

This is the url WebGrab+Plus uses to download the index pages (see 2). Every site uses it own way to compose these url's, but as a rule it contains references to the channel and to the timespan for which it is valid. WebGrab+Plus includes an url_index builder that composes this url based on an entry in the SiteIni file with the following syntax:

url_index{url|stringfragment-1|stringfragment-2| ... |stringfragment-n}

- *url*: just an indication of the type of data that follows, (argument debug supported)
- *stringfragment*: a fragment of the urlstring for the position n. It can be either a fixed string fragment (independent from channel, date or subpage) like http://www.tvgids or one of the 3 types of variable string fragments: channel or urldate or subpage
- *channel*: The reference to the channel for which the url is meant. WebGrab+Plus uses the value of the *site_id* attribute of the channel table in the WebGrab++.config.xml file. Most sites use a simple channel number as *site_id* but some use rather complicated constructions. (e.g. TvGids.nl uses a number 1 for Nederland1, while Skynet.be uses nederland-1?channelid=216 for the same). For most sites a channel list file is provided together with the SiteIni file.
- *urldate*: The reference for the timespan or start date. Most websites have one index page per day. WebGrab+Plus supports this per day timespan style.
  The program also supports multiday e.g. weekly index pages (see also 4.3 , maxdays). In that case the urldate can speci-

fy a start day.
Some other sites however have (occasional) index subpages e.g. when the number of shows of that day exceeds the space of the displayed webpage. In that case the *subpage* reference has be specified:

- *subpage*: Specifies eventual subpages part of the Url. See 4.4.2.2

4.4.2.1 *urldate* format:

The day string that appears at the position of –urldate– depends on the value of a separate SiteIni specification urldate, its syntax:

urldate.format {daycounter|todaynumber} or
urldate.format {weekdaynumber|Sunday-number} or
urldate.format {weekdayname|Monday-name|Tuesday-name|...|Sunday-name} or
urldate.format {datestring|string|optional cultureinfo} or
urldate.format {datenumber|standard|offset} or
urldate.format {list|day1string|day2string|..|daynstring|{other urldate format for following days}}

- *datestrings* follow the .Net standard for datestrings as found in : *http://msdn.microsoft.com/en-us/library/az4se3k1.aspx and http://msdn.microsoft.com/en-us/library/8kb3ddd4.aspx*
- When the *cultureinfo* used for the datestring is different from the one given in the site specification it can be added as option. Assume cultureinfo=nl-NL for the following examples.
- the *list* method is to be used when the Site uses a value like –today– for today rather then a date value. It fills the url with these day strings, eventually followed by whatever urldate format specified for the remaining days.
- the *datenumber* method returns a number that represents a date-time value. It supports the following standards : VBA , the daynumber as used in MS Office ; UNIX , the number of seconds from 1970/1/1 00:00 UTC ; JAVA , the number of milliseconds from 1970/1/1 00:00 UTC ; TICKS , the number of 100 nanoseconds units from 00/00/00 00:00UTC . The offset specifies a time offset w.r.t. to datenumber value. It must be entered as hours like 5:30 or 5.5
- the *weekdayname* method is to be used when the daystring required is a non standard weekday name that cannot be generated by the datestring method.

Some examples to illustrate:
urldate.format {daycounter|0} * output like: 0 1 2 ....
urldate.format {weekdaynumber|0} * suppose today is Tuesday, output like: 2 3 4 ..
urldate.format {weekdayname|lu|ma|mi|ju|vi|sa|do} * suppose today is Wednesday, output like: mi ju vi ..
urldate.format {datestring|yyyy/MM/dd} * output like: 2010/05/10 2010/05/11 ...
urldate.format {datestring|dddd} * output like: dinsdag woensdag ...
urldate.format {datestring|d} * output like: 10-5-2010 11-5-2010 ...
urldate.format {datestring|d|en-GB} * output like: 10/5/2010 11/5/2010 ... (other culture, other standard)
urldate.format {datestring|ddd/dd/MMM/yyyy} * output like: ma/10/mei/2010 di/11/mei/2010 ...
urldate.format {datestring|ddd/dd/MMM/yyyy|en-GB} * output like: Mon/10/May/2010 Tue/11/May/2010 ... (other culture, other standard)
urldate.format{datestring|dddd-dd-MM-yyyy} * output like: maandag-10-05-2010 dinsdag-11-05-2010 ...
urldate.format{list|vandaag|morgen|{datestring|dddd|nl-NL}} * output like (if today is Monday): vandaag morgen woensdag donderdag ...
urldate.format{list|Today|{datestring|d|en-GB}} * suppose today is 9/5/2010 , output like: Today 10/5/2010 11/5/2010 ...

4.4.2.2 *subpage* format:

subpage.format{number(format=xx)|leadstring|first page number|stopstring} or
subpage.format{letter|leadstring|first page letter|stopstring} or
subpage.format{list|subpage-1-string|subpage-2-string|..|subpage-n-string} or
subpage.format{list(format=xx step=stepsize count=countnumber)|startvalue}

- *leadstring*: fixed part of the subpage string.
- *stopstring*: The unique string that occurs on the subpage after the last one valid. When a subpage is specified in the index_url specification, the program will automatically step from one page to the next until the stopstring is detected. After

that the same subpage stepping will start for the next day. If the stopstring is not detected the stepping will stop after 8 subpage tries with a subpage warning and try the next day.

- *startvalue* : an integer for the first subpage value.
  This startvalue may be expanded from the variable 'index_variable_element' (see 4.5.3)
- *stepsize*: an integer number by which the startvalue will be incremented
- *count* : an integer number that determines the number of subpage values in the list.
- *format*: optional, specifies the number format. Default xx=D0
- startvalue , step and count may contain element references from 'index_temp_1 to 6' and 'index_variable_element'

Some examples of to illustrate:
subpage.format {number||1| page not found } * output for subsequent pages: 1 2 3 ..
subpage.format {number|section_|1|page not found} *output: section_1 section_2 section_3 ..
subpage.format {letter|p|a|page not found} * output: pa pb pc ...
subpage.format {list|04:00|12:00|20:00} * output: 04:00 12:00 20:00
subpage.format {list(format=D2 step=6 count=4)|0} * output: 00 06 12 18

4.4.2.3 Full examples of the url_index specification:

Suppose WebGrab++.config.xml channel entry:

<channel update="i" site="tvgids.nl" site_id="1" xmltv_id="NED1-tvgids">NED1</channel>

And the url_index and urldate.format entries in the SiteIni:
url_index{url|http://www.tvgids.nl/zoeken/?q=&d=|urldate|&z=|channel|&t=0&g=&v=0}
urldate.format {daycounter|0} for 3 days will result in:

http://www.tvgids.nl/zoeken/?q=&d=0&z=1&t=0&g=&v=0
http://www.tvgids.nl/zoeken/?q=&d=1&z=1&t=0&g=&v=0
http://www.tvgids.nl/zoeken/?q=&d=2&z=1&t=0&g=&v=0

Another example:

<channel update="i" site="skynet.be" site_id="nederland-1?channelid=216" xmltv_id="NED1-skynet">NED1</channel>

url_index{url|http://www.skynet.be/entertainment-nl/tv/kanalen_|channel|&new_lang=nl&date=|urldate}
urldate.format {datestring|yyyy-MM-dd|nl-BE} for 3 days will result in :

http://www.skynet.be/entertainment-nl/tv/kanalen_nederland-1?channelid=216&new_lang=nl&date=2010-06-22
http://www.skynet.be/entertainment-nl/tv/kanalen_nederland-1?channelid=216&new_lang=nl&date=2010-06-23
http://www.skynet.be/entertainment-nl/tv/kanalen_nederland-1?channelid=216&new_lang=nl&date=2010-06-24

And one using the list method:

<channel update="i" site="tvgids.upc.nl" site_id="Nederland+1" xmltv_id="NED1-upc">NED1</channel>

url_index {url|http://tvgids.upc.nl/TV/Guide/Channel/|channel|/|urldate}
urldate.format {list|Today|Tomorrow|{datestring|dddd|en-GB}} today being Tuesday, for 3 days will result in :

http://tvgids.upc.nl/TV/Guide/Channel/Nederland+1/Today
http://tvgids.upc.nl/TV/Guide/Channel/Nederland+1/Tomorrow
http://tvgids.upc.nl/TV/Guide/Channel/Nederland+1/Thursday

A subpage example:

<channel update="" site="plus.es" site_id="PLAYDC" xmltv_id="PlayDisney">PlayDisney</channel>

url_index{url()|http://www.plus.es/guiatv/resultados.html?tipo=dh5&frm=B&dia=|urldate|&c%5B%
5D=|channel|&f=TO&pr=L|subpage}
urldate.format {datestring|yyyy-MM-dd}
subpage.format {number|&pag=|1|No hay ningún título que cumpla con las condiciones de la búsqueda}

Supposing this channel has 2 subpages this will result in :

http://www.plus.es/guiatv/resultados.html?tipo=dh5&frm=B&dia=2010-09-30&c%5B%5D=PLAYDC&f=TO&pr=L&pag=1
http://www.plus.es/guiatv/resultados.html?tipo=dh5&frm=B&dia=2010-09-30&c%5B%5D=PLAYDC&f=TO&pr=L&pag=2

http://www.plus.es/guiatv/resultados.html?tipo=dh5&frm=B&dia=2010-09-30&c%5B%5D=PLAYDC&f=TO&pr=L&pag=3
(detects the stopstring —> step to next day)
http://www.plus.es/guiatv/resultados.html?tipo=dh5&frm=B&dia=2010-10-01&c%5B%5D=PLAYDC&f=TO&pr=L&pag=1
http://www.plus.es/guiatv/resultados.html?tipo=dh5&frm=B&dia=2010-10-01&c%5B%5D=PLAYDC&f=TO&pr=L&pag=2
http://www.plus.es/guiatv/resultados.html?tipo=dh5&frm=B&dia=2010-10-01&c%5B%5D=PLAYDC&f=TO&pr=L&pag=3
(detects the stopstring —> stop, last page of last day)

4.4.3 other url elements

The next important url is the one that points to the show detail page and possibly the show subdetail age. Normally there is some kind of hyperlink with a <a href= tag that points to it but not always the complete url is found there. The SiteIni specification for url's other than the url_index (above) allows to add the missing components if necessary:

url-elementname {url(optional arguments)|leadstring|bs|optional es|ee|optional be}

- url-elementname: Can be either *index_urlshow*, (*index_)urlsubdetail* and *index_urlchannellogo* (optional)
- url : just an indication of the type of data that follows, (argument debug supported)
- leadstring: The invariable part of the url that sometimes misses from the html link
- the remaining parts |bs|optional es|ee|optional be are the normal scrubstrings

Example for show Max Geheugentrainer on site tvgids.upc.nl

index_urlshow {url|http://tvgids.upc.nl|<a href="||">} results in
http://tvgids.upc.nl/TV/Guide/Programme/9184772/MAX_Geheugentrainer/Nederland+1/

And an example without a leadstring of the same show on site skynet.be:

index_urlshow {url||<a href="||">} results in
http://www.skynet.be/entertainment-nl/tv/tv-gids/detail_max-geheugentrainer?programkey=MagnetMedia__11435188
(notice that the 'empty' leadstring || is required!!)

4.4.3.1 multiple subdetail pages

Sometimes when a subdetail page is used by a site the data is split over more than one subdetail page. In that case it is possible to define multiple urlsubdetail elements. The program will grab each of these pages and add all of them in one result. The subdetail elements can be grabbed from that combined page . Example of multiple urlsubdetail element specification:
urlsubdetail.modify {addend|'index_urlshow'takepart.html}
urlsubdetail.modify {addend|####'index_urlshow'members.html}
urlsubdetail.modify {addend|####'index_urlshow'comments.html}
urlsubdetail.modify {replace()|####|\|}
The last line replaces the element separator placeholder #### by the | character that is used the program to separate multivalue element values. (see 4.6.1.3 for explanation about this element separator character |)

4.4.4 the FTP and File protocol

4.4.4.1 FTP

The program also support the FTP protocol. The configuration is very simple, just replace *http://* in the url element specification by *ftp://.* The program will automatically configure a FtpWebrequest .
Example: url_index{url|ftp://ftp.pop-tv.si/|channel|_|urldate|_####_EPG.XML}
If the site requires user identification by means of a name and password , issue a credentials header: url_index.headers {credentials=name, password}

4.4.4.2 File

Mainly for testing and debugging it can be usefull to get a local file into the program. Like this:

url_index {url|file:||computername|path|filename} or *url_index {url|||computername|path|filename}*

4.5 Data needed to scrub xmltv elements from the downloaded pages

There are:

- the elements scrubbed from the index page , element name prefix *index_*
- the elements scrubbed from the show-detail page, *no element name prefix* or *detail_*
- the elements scrubbed from the sub-detail page, element name prefix *subdetail_*

The program allows most elements with the same xmltv target element, to be scrubbed from any or all of these three html pages. If the program finds more than one scrubspec for a certain element any result will be added together in a way that depends on the if it concerns a *multiple value xmltv* element or not (as discussed in 1.3 and 4.2.3)
All scrub specifications of these sections follow the syntax as explained in section 4.2 with the action specifier *scrub* :

elementname.scrub {type(optional arguments)|bs|optional es|ee|optional be}

4.5.1 Non optional elements - elements needed by the program

See for more details the element name table in APPENDIX D, unchecked column *optional*

- index_showsplit

  This is not a regular xmltv element, (it has no xmltv name), but is required for the proper operation of the xmltv update process.
  As explained in section 2, WebGrab+Plus uses the show data on the index page to determine if an update of the xmltv file is necessary for that particular show. To do that it first splits the index page into parts, one for each show. For that it needs the – index_showsplit - scrub specification that returns all those show parts as result.
  Normally, the indexpages list the shows of one day in ascending start-time order. Some sites however list shows of several days on one page (multiday indexpage, see also 4.3, *maxdays*). As a complication it occurs that the shows on these multiday indexpages are not listed in pure ascending start-time order but in day section fragments (like morning, afternoon, evening etc.), e.g. first all morning shows of all days followed by all afternoon shows of all days etc.
  The program provides two options to sort the shows on this type of multiday index pages:

  ** First option: With the special attribute *sort@.* This will sort the shows in ascending time order. It can be used if the division into the day section fragments occurs at fixed times of the day (e.g. the evening section always start at the first show after 20:00). In that case enter :

  index_showsplit.scrub {type(sort@time-1, time-2, ..,time-n)|. . . .}

  It can also be used if the division always occurs at — or immediately after - the next full- or half-hour following the last show of the previous day section. In that case enter for fullhour :

  index_showsplit.scrub {type(sort)|. . . .} or
  index_showsplit.scrub {type(sort@fullhour)|. . . .}

  and for half-hour:

  index_showsplit.scrub {type(sort@halfhour)|. . . .}

  ** Second option: By scrubbing the each day section fragment on the indexpages separately. Like , if the index page is split in a day-section and an evening-section :

  index_showsplit {type(optional timespan=hours)|day-section-scrubstrings}
  index_showsplit {type(optional timespan=hours)|evening-section-scrubstrings}

  Each scrub will result in an array of shows and the resulting arrays will be merged into one in ascending start time order. The program will attempt to determine the time structures of the arrays automatically. In some cases it can help to specify a *timespan* attribute, which is the approximate duration of each day section. E.g. if the day-section is from 05:00 to 18:00, specify timespan=13:00 and if the evening/night-section is from 18:00-05:00, specify timespan=11:00
  Adding the attribute *debug* during the development phase will show the result of the sorting in the log file.

  Experience learned that the order in which the shows in the index pages occur can have nearly every imaginable form. The following 'specials' have occurred (and are handled by the program):

⇒ overlaps between subsequent index pages. The duplicate shows are normally removed automatically by the program, but only if the remaining of the pages are in the normal 'starttime' ascending order. If not, one can use the command *cleanup(removeduplicates)* , see 4.6.4.6

⇒ multi day index pages with an order of fixed timeframes (in which more that one show can start), spread over the

days in a regular pattern. Here the command *substring(type=element)/start length/repeat* can be used to rearrange the timeframes and the shows in it. See 4.6.4.3

⇒ fully random or reverse order of the shows in the index page.
Use the command *sort(ascending/descending,string/integer).* See 4.6.4.9

⇒ a mix of index shows of different channels. Use the command *select/string operator* to filter the shows to keep. See 4.6.4.8

– index_start , xmltv element *–start-*
Scrubs the start time of the show, essential for both the xmltv output file as for the update decision process of the program

– index_title *, compared with* xmltv element *–title-*
The show title is found on two places in most sites, on the index page and on the show detail page. The latter is the most accurate and is used by WebGrab+Plus for the xmltv element *-title–* . The index_title is used (and essential) for the xmltv update decision process.
Because some sites have 'varying' differences between both show titles and because WebGrab+Plus compares the index-title with the title in the existing xmltv listing (which originates from the show detail page), a one to one comparison is not possible due to these differences. WebGrab+Plus uses a smart-comparison which results in a titlematchfactor as detailed in 2.1.
If a site lists a combination of elements together with the index_title (like es *category, title, subtitle* ee or other combinations including the title) it is best to scrub them with a separator argument without include or exclude arguments! This yields all these elements in the index_title. The title comparison is smart enough to find the real title within this combination. See also 4.3
In rare cases, a site has no comparable titles on index— and detail page. In such cases the title comparison can be disabled by specifying *titlematchfactor=0*

4.5.2 Elements that are processed in a special way

– index_date (optional) , part of xmltv element *-start-* and *-stop-*
Scrubs the date from the first index page which is the date of the first day of the timespan for - which the shows will update. If no index_date scrubspec is entered in the SiteIni file the date of — today– is taken. By default the scrubbed date value is only used as a check if the first grabbed index page is from 'today' . If not, the scrubbing of the shows will be stopped with an error message. When the dedicated argument *force* is added to the scrubstring, the scrubbed date value will be used as the date of the first show on the index page. The date of the following days is calculated by the program.

– index_stop (optional) , xmltv element *–stop-*
Scrubs the stop time of the show. Because not all Sites provide this information (relying on the start time of the next show for it), WebGrab+Plus does the same if no scrubspec is entered in the SiteIni file. The resulting value either from direct scrub or from substitution is essential for the xmltv update decision process.

– index_duration (optional) *,* xmltv element *–stop-*
Alternative for index_stop. Some Sites specify this rather than the stop time. WebGrab+Plus calculates the stop time from stop=start + duration. For that it must be in the format hh:mm. (The operations discussed in 4.6 provide ways to convert it to this format if it isn't)

– titleoriginal (optional) *,* xmltv element *–title-*
See also 4.2.5.6 Dedicated arguments.
It is meant to allow multiple titles for different languages. The scrubstring can include the dedicated argument *lang* .The syntax of it is :

lang or lang=xx (xx=two letter language spec like *en* for English)

If a *lang* argument is given without a language value or with the value "xx" or if no *lang* argument is added, the title lang attribute in the xmltv will be lang="xx", which is supposed to indicate the 'original' show title in an unspecified language. If a two letter language spec is provided it will use that in the xmltv lang= attribute.

Example:
title.scrub {single |scrubstring-1}
titleoriginal.scrub {single (lang=en)|scrubstring-2}
could result in something like:

<title lang="es">Mujeres Desperadas</title>
<title lang="en">Desperate Housewives</title>

- productiondate (optional) , xmltv element *–date-*
  The productiondate should yield the year of the production of the show. Because it is often hidden inside another element, like the description it is rather difficult to find unique element separators. WebGrab+Plus will scrub the first 'year' value (yyyy) between the element separators automatically.
- *Boolean type elements* (optional) like , subtitles (xmltv element *–subtitles-*), premiere (xmltv element *–premiere-*)and previousshown (xmltv element *–previously-shown-*) :
  These elements have no value in xmltv, they are either listed , like *<premiere/>,* or not listed.
  The program needs the value *true* to add a listing to the xmltv file. If this required value cannot be scrubbed directly (because it is listed differently in the html page) , use a modify operation (see 4.6) to replace the actual value with *true.*
  E.g. like:
  subtitles.modify {replace(not "")|'subtitles'|true}

4.5.3 Special elements (see APPENDIX D)

- temp elements :
  temp_1, temp_2, temp_3, temp_4, temp_5, temp_6 . Available for each of the three prefix versions.
  These special elements have no direct xmltv destination. They can be used to temporary scrub and store data that is later used together with the action specifier *modify* (see 4.2.3 and 4.6) to alter or create other elements.
- index_variable_element
  This special element has no direct xmltv destination. It can be used if any of the other scrubstrings requires a value that varies (e.g. with each channel or day). Its value can be scrubbed (from the un-split index-page) and modified. It is the only element that :
  a. can be used in a scrub string as part of bs es ee or be like in :
  index_variable_element.scrub {single|Billing\t\n||\t|\t} * scrubs the value from the index page and uses it to split the index pages in shows :
  index_showsplit.scrub {multi|'index_variable_element'||\n}
  b. they can also be used in *argument* values like:
  index_showsplit.scrub {multi(includeblock='index_variable_element'|"column">|time">||}
  c. allows to pass certain channel values from the config file with a modify command (see 4.6 for details about the modify command) like in :
  index_variable_element.modify {addstart|'config_site_id'}
  This line copies the site_id for the actual channel from the channel list in the config file.
  Other supported config values are :
  - the *xmltv_id* entered as 'config_xmltv_*id*'
  - the *display_name* entered as 'config_display_name'
  - the *site_channel* entered as 'config_site_channel'
  - the *credentials* entered as 'config_credentials_user' and 'config_credentials_password'
  - and *timespan* entered as 'config_timespan_days'
  d. allows to pass date/time read-only values *urldate, now* and *showdate.* (see APPENDIX D, read-only elements)
- index_site_channel and index_site_id. When specified, a channel-list file will be created automatically. This is a file that lists the available channels of the site, in a format that can be copied directly into the config file WebGrab++.config.xml. These files are supplied together with the SiteIni file when downloaded from http://www.webgrabplus.com/epg-channels. As default, the allocation of the values of these elements in for channel specification in the config file WebGrab++.config.xml will be as follows:
  <channel update="i" site="site" site_id="index_site_id" xmltv_id="index_site_channel">index_site_channel</channel>
  With the dedicated argument *alloc* it is posible to change the allocation of these values. This argument accepts only three values : *site_id, xmltv_id* and *display_name* E.g. (*alloc=site_id,display_name)*
  These elements are scrubbed from the un-split index-page by default. If the channellist data is located on another page the url_index specification must be overruled by specifying the one for this page after the one for the tv-program data. When the channel data if found on more than one page subpages can be used. (see 4.4.2.2).
- sort_by This must be specified when using the command *sort* (see APPENDIX D and 4.6.4.9 Sort). It must have the value of that part of the multivalue element by which it is to be sorted. The argument *target* links it to the multivalue element to sort. It can be scrubbed and modified.

4.5.4 Read_only elements (see APPENDIX D)

Elements that pass parameter values from various sources in operations. Cannot be scrubbed or modified.

- previous value elements: In these elements the value of the previous scrub is stored. The program automatically stores the values of previous scrub of the following elements: *index_start, index_stop, index_duration, temp_1* to *–6.* These values can be recalled by adding an additional prefix *previous_* to the element names.
  A typical use is when a site displays indexpages graphically, each next show in a horizontal grid, the start and stop times hidden in pixel coordinates, then it is necessary to know the previous value of time elements to calculate the actual start and stop time. (See APPENDIX D and 4.6.4.5 Calculate)
- urldate Passes the urldate value (unformatted!) of the url_index with which the actual page is grabbed. The returned value must be formatted to the required format using the format argument (see 4.6 arguments).
- now Passes the date and time value (unformatted!) of the actual moment. The returned value must be formatted to the required format using the format argument (see 4.6 arguments).
- showdate Passes the epg date value (unformatted!) of the actual show being grabbed. Warning! It is obvious that this will only return a value after the start time of the show is grabbed! The returned value must be formatted to the required format using the format argument (see 4.6 arguments).
- config_site_id Passes the value of the site_id of the channel as specified in the config file.
- config_site_channel Passes the value of the site_channel of the channel as specified in the config file.
- config_xmltv_id Passes the value of the xmltv_id of the channel as specified in the config file.
- config_display_name Passes the value of the display_name of the channel as specified in the config file.
- config_timespan_days Passes the value of the days component of the timespan in the config file
- config_credentials_user Passes the username of the credentials for the actual site in the config file
- config_credentials_password Passes the password of the credentials for the actual site in the config

4.6 Operations: Optional data that allows post modification of the scrubbed xmltv elements.

Action specifier: *modify*

With the data in this section of the SiteIni file it is possible to modify already scrubbed elements and/or obtain a value by other means than scrub from a html page. The elements for which these modifications are supported are listed in APPENDIX D. The syntax to specify such a modification :

elementname.modify {commandname(optional arguments)
|optional expression-1|optional expression-2}

- element name : Any of the elements listed in APPENDIX D for which the action specifier modify is allowed.
- modify : the action specifier for this type of operation
- commandname, either :
  - replace : replaces the value of expression-1 with that of expression-2 (see 4.6.4.1)
  - remove : removes the value of expression-1, no need for expression-2 (see 4.6.4.2)
  - substring : extracts a part of expression-1, no need for expression-2 (see 4.6.4.3)
  - addstart : adds the value of expression-1 to the start of the element, no need for expression-2 (see 4.6.4.4)
  - addend : adds the value of expression-1 to the send of the element, no need for expression-2 (see 4.6.4.4)
  - calculate : performs a set of calculations, expression-1 is an arithmetic expression, no need for expression-2 (see 4.6.4.5)
  - cleanup : tidying up of elements, no expressions (see 4.6.4.6)
  - clear : to erase the content of any element (see 4.6.4.7)
  - select : to select certain members of multi value elements (see 4.6.4.8)
  - sort : to sort multi value elements (see 4.6.4.9)
- arguments
  - conditional arguments: There are two possible sets of conditional arguments
    - *Pre-conditions* that needs to be true for the operation to be performed. They are evaluated first. It allows to evaluate the value of any element or compare element values with constants or other elements. (see 4.6.2.1)
    - *Post-conditions*, simple condition that only evaluate the value of the element to be modified before or after the

operation. (see 4.6.2.2)

- debug : Adding the word debug as argument will start logging of the modify process for the element in the WebGrab++.log.txt file.
- format : Specifies the output format for the calculate command. (see 4.6.4)
  - Numeric formats: Supported values are all the standard numeric format strings F and D, as described in http://msdn.microsoft.com/en-us/library/dwhawy9k.aspx like format=F0.
    Default is F2 (two decimal digit fixed point, like 16.35).
  - Date and Time formats: Also supported is format=time, format=date , this will convert the numeric value in HH:mm and yyyy/MM/dd respectively as default date-time format. For other formats, add a comma and date-time format string after the word time or date, like format=time,h:mmtt or format=date,dd/MMMM/yy
    See http://msdn.microsoft.com/en-us/library/8kb3ddd4.aspx for date-format strings.
  - Extra Date formats: Besides these standard date formats the following numeric date formats are supported:
    - format=date,vba Returns the excel-vba day-number, as used in MS-Office
    - format=date,unix Returns the number of seconds from 1970/01/01 00:00 UTC
    - format=date,java Returns the number of milliseconds from 1970/01/01 00:00 UTC
    - format=date,ticks Returns the number of 100 nanosecond units fom 00/00/00 00:00 UTC
    - Adding utc as prefix, like format=utctime or utcdate will return the utc time or date (ignoring the timezone utc offset)
  - The timespan format allows conversion and calculations of timespans. It must be entered as format=timespan. The default format is in days and will result in a string d:h:m
    When specified as format=timespan,hours a string h:m is the result.
  - Finally there is format=productiondate. When entered it will return the first 4 digit numeric value it finds in string-1 that is between 1900 and 'nextyear'.
    Example: productiondate.modify {calculate(format=productiondate)|'description'}
- type : When expression-1 is specified by means of place-indices and command is remove, replace or substring, it specifies the index-base. (see 4.6.1.4 Expression-1 with indices).
  It is also used with command calculate - index-of (4.6.4.5.2) and count (4.6.4.5.1).Possible values are :
    - type=string (default, expression-1 is specified as string, no indices)
    - type=char (the indices specify character positions or length)
    - type=word (the indices specify word positions or length)
    - type=sentence (the indices specify sentence positions or length)
    - type=paragraph (the indices specify the paragraph position or length)
    - type=element (the indices specify element positions or length in the case of multi value elements, see 4.6.1.3)
    - type=regex must be used to indicate the use of a regular expression in expression-1 (see expression-1 and –2 components further down in this chapter)
- separator : This specifies a separator string value that is used when converting multi value elements to a combined single value. It can be used together with the commands remove, replace, addstart and addend.
  If this argument is entered, the operation will try to convert the result in a single value string, adding the separator string between the multi value components. (see 4.6.1.3 Multiple value elements and modify)
- style : This argument can be added to the cleanup command (see 4.6.4.6) to specify the required style of the cleanup result. Possible values are :
    - style=sentence (converts this is a sentence. In This is a sentence.
    - style=name (converts john do in John Do)
    - style=upper (converts to UPPERCASE)
    - style=lower (converts to lowercase)

  Beside these basic styles , the specials:
    - style=regex, formats the input as a regular expression, inserts the required escape codes
    - style=urlencode and style =urldecode , formats the input string as an url string or the reverse
    - style=uniencode and style=unidecode , converts unicoded character sequences to the actual chars and reverse.
    - style=jsondecode, converts json encoded strings back to normal
    - style=sha256encode, style=md5encode and style=base64encode provides encoding for encrypted

internet communications.

- removeduplicates : To be used with command cleanup to remove possible duplicates from multi value elements. (see 4.6.4.6.1)
- link : Links elements when used together with removeduplicates in command cleanup (see 4.6.4.6.1)
- tags : To be used with command cleanup to remove strings enclosed by specified start– and end- strings. (see 4.6.4.6.2)

– expression-1 and -2 components, these expressions can be composed with:

- *text* : all characters with exception of | { and '
  If any of these are needed in the string they have to be preceded by the backslash character \, like O'Neil must be entered as O\'Neil
- *element* : to be entered between '' , like 'title' or 'temp_1',
  the value of the element will be inserted in the expression result.
- *scrubstring*: to be entered between '{ }'
  like '{single|<a ref=|<p>|</>|<table}'
  The use of a scrubstring in this way has a small limitation: The scrub is performed from the same html page as from which the element is originated. So, in case of an element from the index page the scrub entered here is also done from the index page. In most cases it is easier and more flexible to use the 'temp' and 'index_temp' elements instead. See also 4.6.1.1 for limitations.
- *indices* : Expression-1 only.
  Can be used to extract (with commands *substring* and *replace*) or remove (with command *remove)* parts of a source string.
  The use of indices must be accompanied by the argument *type* to specify the index-base (see above; arguments). Indices must be entered as (integer) numbers. Each of these numbers can also be entered as element enclosed by ''. The first number represents the *start* position, the second (optional) number the *length* and the third (optional) the *repeat*. (see for more details 4.6.1.4 Expression-1 with indices)
- *regular expressions* : Expression-1 only.
  As with indices (see above) these can be used together with the commands *substring, replace* and *remove.* To initiate the use of it they must be accompanied by argument *type=regex.* For more information about the use of 'regular expressions' see 4.2.1.2 and 4.6.1.5 (Exression-1 with 'regular expressions')
- *arithmetic expression* in the case of command calculate (see 4.6.4).
- combinations of text, element, scrubstring, indices and arithmetic expression.
  See 4.6.4 , the commands, for examples.

4.6.1 Notes and examples of the effects of *modify*

4.6.1.1 The order of the actions and the argument *scope*.

Webgrab+Plus executes the scrubbing and modifying of the elements in a certain order. Some of these steps have a named reference called *scope*, which purpose will be discussed later in this section. Roughly the order of actions is like this:

1. *scope=urlindex* , compose/modify the url_index and grab the index-page(s)
2. *scope=datelogo* , scrub/modify index_date, index_variable_element and index_channellogo
3. *scope=splitindex* , split/modify the index-page(s) in index shows
4. Step through the index shows one by one
5. *scope=indexshowdetails* , scrub/modify all other index_ elements from the index show.
6. Update decision. If no update - - back to 4, next index show
7. if: it is an index_only channel or: if no valid urlshow is scrubbed,
   back to 4, next index show
   or else :
8. grab the show-detail page
9. *scope=showdetails* , scrub/modify all show-detail elements
10. if: a valid urlsubdetail is scrubbed,
11. grab the sub-detail page
12. *scope=showsubdetails* , scrub/modify all sub-detail elements
13. compose the xmltv elements and write them to the xmltv output file
14. if more shows, back to 4, next index show. Else: next channel.

Not in this order , but with its own scope:

0. *scope=channellist* , scrub/modify a channellist file

- The order in which the scrubbing of the elements is done (in actions 2. 5. 9. 12. and o.) is fixed by the program, not important for the results and independent of the order of the scrubstrings in the SiteIni file.
- The order in which the modify operations are done (in actions 2. 5. 9. and 12.) is determined by the order in which the modify operations (for that group) are listed in the SiteIni file. E.g. in 5. , the modification of all index_elements other than index_date, index_variable_element and index_channellogo is done. It will modify these in the order they occur in the SiteIni file.
- The range of actions for which an operation of elements is executed is called *scope.*
- Some general supporting elements , like the index_temp and index_variable_element have a wider scope (*urlindex, datelogo, splitindex* and *indexshowdetails*), because they are used as supporting elements for others. Because of this operations specified for these supporting elements will be executed at all these actions even when the operation is meant only for one of them. This can lead to unexpected results and unnecessary consumption of processing time. To avoid this the argument *scope* can be added to the operation (see 4.6.1.2).

It is important to realise that this order will *influence the result* and also *poses restrictions* on the use of other elements in the modify operation. For the influence on the *result* consider the following :

Suppose : *description = A short story*
Case 1.
temp_1.modify {calculate(format=F0)|'description' " " #} ———> result temp_1 = 2
description.modify {remove|short } ———> result description = A story

Case 2.
description.modify {remove|short } ———> result description = A story
temp_1.modify {calculate(format=F0)|'description' " " #} ———> result temp_1 = 1

These simple cases illustrate that modify operations work on bases of the results of previous modify operations.

This also explains the *restrictions* : Operations that try to use elements that have no value (as yet) will not work. Like trying to use (non index_) elements in 5. , scope indexshowdetails. That can't work because these element are not yet scrubbed, that occurs later in 9. , scope showdetails
Consider the following:

A site has only show-detail links for a limited number of shows. We scrub both
index_description and description to get a description in both cases. That could create a double description in case of a show with a show-detail link. So, we would like to erase the
index_description if the description is not empty. It is only logical we try this:

index_description.modify {remove('description' not "")|'index_description'}

That, unfortunately, will not work because this operation is done in 5. and uses an element (description) that is only available after 9. A way to solve this particular case is :

index_description.modify {remove('index_urlshow' not "")|'index_description'} (It tests for the show-detail link – index_urlshow- to exist which value is available in 5.)

4.6.1.2 The use and effect of argument *scope*

As explained in 4.6.1.1 the scope of an operation is the (range of) steps (also detailed in 4.6.1.1) at which the operation is executed. By adding the argument *scope* to the specification of the operation the scope can be narrowed to a certain (just one) step. The syntax:

element.modify {command(scope=string other-arguments)|..}

- string: one of the following *urlindex datelogo splitindex indexshowdetails showdetails showsubdetails channellist* (see 4.6.1.1)

If a group of subsequent operations in the SiteIni should be set to the same *scope, scope.range* can be used. The syntax of that:

scope.range {(string)|end} combined with end_scope
- or - scope.range {(string)|lines}

- string: one of the string as given above
- end : the word *end* indicates that the program expects end_scope after the last operation that belongs to the group for which the scope have to be set.
- alternatively the number of *lines* (containing operations) can be specified.

4.6.1.3 Multiple value elements and modify

Some explanation about the internal handling of elements: Most elements can have more than one value, either through separators, through multiple scrubs or by being a multi type scrub. Internally they are not stored as array but as a combined string with the | character as separator. Thus, an element with the values AAA BBB ccc ddd will have the internal representation AAA|BBB|ccc|ddd It depends on another element property , multiple xmltv value, true or false, how these values will be written to the xmltv file. If true (multiple), they will get multiple xmltv elements like:

```
<element>AAA</element>
<element>BBB</element>  etc.
```

If false, they will be added together, separated by a period-space, like:

```
<element>AAA. BBB. ccc. ddd.</element>
```

How does this effect result of *operations?*
For this, the argument *separator* plays a determining role.
In operations, all elements, in any of the expressions-1 or –2, are considered multi value elements (a single value element as a multi value element with just one value). Each value is evaluated for the requested operation individually, one at the time. At the end of this process, when the expression is assembled, the resulting components are 'added' together, separated by the string specified by the *separator* argument. (see 4.6 , arguments). This results in two effects:
- If no *separator* argument is entered, or if its value is "\|", the before mentioned multi value separator | is placed between the components. The effect of this is described at the start of this section, it keeps its potentially multi-value nature.
- Any other value of the *separator* argument will combine the components in a single string, with this separator string between them.

Multi Value Elements examples:					
	element-to-modify.modify{command(argument)|expression-1|expression-2}				
element-to-modify	*element*	*command*	*argument*	*|expression-1 | expression-2*	*result*
Abc def.	Ghi|Jkl|Mno	addstart		|'element'. |	Ghi|Jkl|Mno. Abc def.
Abc def.	Ghi|Jkl|Mno	addstart		|'element'||	Ghi|Jkl|Mno|Abc def.
Abc def.	Ghi|Jkl|Mno	addstart	separator=" & "	|'element'. |	Ghi & Jkl & Mno. Abc def.
Abc def.	Ghi|Jkl|Mno	addend	separator=", "	|'element'. |	Abc def. Ghi, Jkl, Mno.
Abc|Def	Ghi|Jkl	addend	separator=", "	|* 'element'. |	Abc*Ghi, Jkl.def*Ghi, Jkl.
Ghi, Jkl, def, Mno.	Ghi|Jkl|Mno	remove	separator=", "	|'element'. |	def,
- empty -	Ghi|Jkl|Mno	addstart		|'element'|	Ghi|Jkl|Mno
Abc|Def|Ghi	Ghi|Jkl|Mno	remove		|'element'|	Abc|Def
Abc|Def|Ghi	Ghi|Jkl|Mno	replace		|'element'|Xyz	Abc|Def|Xyz
Abc|Def|Ghi	Ghi|Jkl|Mno	replace	separator=" & "	|'element'|Xyz	Abc & Def & Xyz

4.6.1.4 Expression-1 with indices

Indices in *expression-1* are only supported in combination with the commands *remove, substring* and *replace.* (not with commands *addstart, addend, cleanup* and *calculate)*

- Indices in expression-2 are not allowed.
  As explained in 4.6 - arguments, the argument *type* sets the base of indices used in *expression-1.* (see 4.6 expression-1 and -2 components, indices). These indices specify the position and the length (or number-) of a character (in case of *type=char),* or a word (in case of *type=word),* or a sentence (in case of *type=sentence),* or a paragraph (in case of *type=*paragraph) or an element value (in case of *type=element)* (which only makes sense for *multi value elements*).
- The basic structure and syntax of *expression-1* containing indices is :

  (type=xxx)|'element' startpos optional-length}

  Between 'element' startpos and optional-length a space is needed. If 'element' is the same as the element-to-modify, it can be left out of *expression-1*

(type=xxx)|startpos optional-length}

- *length* is optional. If left blank, the length to the end is taken.
- *startpos* can be negative, in that case the position counting from the end backwards is taken.
- *startpos* and/or *length* can also be entered by way of '*element*' in which case the integer value of '*element*' is used. In this case the element-to-modify cannot be left out! (see also 4.6.4.5.1 # Count and 4.6.4.5.2 @ Index-of)

Indices examples:	Red = selected parts		Blue = not selected		
---> with command substring and remove:		element.modify {command(type=xx separator=xx)|expression-1}			
			expression_1	command *substring*	command *remove*
	element value	*separator*	*type*	*indices*	result:	result:

multi start	Abc def|Jkl mno pqr|Stu vwx		element	0,2 1	xyz	xyz|Jkl mno pqr|xyz

The effect on the value of element to modify can best be described with :

'*substitute the actual value with the result of the expression*'

This is also the case if the *element-to-modify* is another than '*element*' :

element-to-modify.modify {command(type=)|'element' indices}

'The resulting value of the *element-to-modify* will be the result of *expression-1*'

The original value of element-to-modify will be substituted.

Beside the basic structure and syntax, more complex forms are supported:

|startpos-1,startpos-2,..,startpos-n length/repeat} and of course

|'element' startpos-1,startpos-2,..,startpos-n length/repeat}

- *repeat* The startpos at which the sequence is repeated. Default is full length (no repeat)
- multiple *startpos* values must be separated by comma's.
- *startpos, length* and *repeat* maybe entered as 'element'

The table in this section illustrates the results of the expressions with indices.

4.6.1.5 Expression-1 with 'regular expressions'

For a short general introduction of 'regular expressions' see 4.2.1.2

Similar to indices, general expressions in *expression-1* are only supported in combination with the commands *remove, substring* and *replace .* They are not allowed in *expression-2*.

To indicate that *expression*-1 contains a regular expression the argument *type=regex* is required. A regular expression in an operation must be enclosed by " ".
A regular expression may contain elements, enclosed by ' ' which value may in itself contain parts of - or whole regular expressions, like:

"regex-part'element-containing-a-regex-part'regex-part . . .etc"

Following are possible entries:
For the commands *substring* and *remove:*

Element-to-modify.modify {command(type=regex)|"regular-expression"}

If element contains the 'source data'

Element-to-modify.modify {command(type=regex)|'element' "regular-expression"}

For command *replace* add expression-2 to any of the entries above, like:

Element-to-modify.modify {replace(type=regex)|"regular-expression"|expression-2}

Example: Suppose the title contains the names of the director and a list of actors that must be removed and moved to the appropriate elements:

Title : *The "Pelican Brief" dir.: Alan J. Pakula, starring: Julia Roberts, Denzel Washington*

This will remove director and the actors and places them in where they belong:

```
actor.modify {substring(type=regex)|'title' "(?:starring): *(.*?)(?:, *(.*))"}
title.modify {remove(type=regex)|"((?: starring): *(?:.*?)(?:, *(?:.*)))"}
director.modify {substring(type=regex)|'index_title' "(?:dir\.):\s*(.*?),"}
title.modify {remove(type=regex)|"((?: dir\.):\s*(?:.*?),)"}
```

4.6.2 Conditional arguments

4.6.2.1 Pre-Conditional arguments

These conditions are evaluated first. If true the operation is executed. The following conditional *operators* can be use:

=	string, equal ?, ignore (lower or upper) case , this operator is default and the = character can be omitted
==	string, equal ?, match case
~	string, contains ?, ignore case
~~	string, contains ?, match case
not	added to one of the operators above (not= not== not~ and not~~) reverses the result
>	numerical, more ?
<	numerical, less ?
>=	numerical, more or equal ?
<=	numerical, less or equal ?

The syntax :

('compare-this-element' operator to-this)

- 'compare-this-element': The element to evaluate. Enter the name of the element enclosed by ''. If omitted, the element-to

-modify is taken. In the case of the numerical operators > < >= and <=, the element entered will be converted to a floating point number (the floating point conversion of the first number in the string - or 0 (zero) if it does not contain any numerical value)

- operator : one of the conditional operators listed above
- to-this : A "string" (enclosed by "") or an 'element' (enclosed by ''), in which case it will be expanded to the value of the element. These to-this strings may contain wildcards (see 4.2.6)

A few examples:

('element' "abc") result 'true' if the value of element is abc or Abc etc
('element' == "abc") result 'true' if the value of element is abc, false if Abc etc
('element' ~ "abc") result 'true' if the value of element contains abc or ABC etc
('element' ~~ "abc") result 'true' if the value of element contains abc, false if ABC etc
('element' not ~ "abc") result 'true' if the value of element doesn't contain abc
('element' "") result 'true' if the value of element is "" (empty)
('element' 'other-element') result 'true' if the value of element is the value of other-element
('element' ~ 'other-element') result 'true' if the value of element contains the value of other-element.

Examples when 'element' is left out and the element to modify is taken :

element.modify {addstart('other-element')|abc} 'true' if the value of element is the value of other-element, then abc will be added.
element.modify {addstart(not ~ "abc")|abc} 'true' if the value of element doesn't contain abc, then abc will be added.
element.modify {addstart("")|abc} 'true' if the value of element is "" (empty), then abc will be added.

Example of numerical conditional arguments:

('element' < "10") 'true' if the first numerical value in element is smaller than 10. E.g. if element = "Episode 9"

4.6.2.2 Post-Conditional arguments

These conditions will only be evaluated if the pre-conditions are *true* (or left out).
Values : either *anycase, null* or *notnull*

- *anycase (default)* : the operation will be performed regardless any of the conditions described below.
- *null* : the operation will only be performed if the element is *null* (in the case of addstart and addend commands)
- *notnull* : the operation will only be performed if the element is *not null* in the case of addstart and addend commands
  : the operation will *not* be performed if the element will become *null* during/through the operation in the case of replace and remove commands

4.6.3 Loops

Loops allow to run a set of operations for a number of times or until a certain condition is met.
The syntax:

loop {(optional-condition optional-max)|lines} or
loop {(optional-condition optional-max)|end} combined with end_loop

- - *(optional) condition* : E.g. 'description' ~ "abc" . Must be *true* while the loop is running, when *false* the loop ends and the operations continue after the last line of the loop. Any of the *pre-conditional-arguments* (as in 4.6.2.1) can be used to specify this condition. When no condition is specified its value is assumed *true.*
- *(optional) max* : E.g. *max=6 .* Can be used to set the number of times the loop will run if no condition is specified or when the loop doesn't end with a condition value *false* before reaching this *max* value. If *max* is not specified its default value is assumed 100. This value is 'zero' based, hence max=6 will run the loop 7 times.
- *lines* : The number of lines (following the line specifying the loop) that are contained in the loop.
- *end* : Alternative to *lines* specify the word *end* in combination with *end_loop* after the last line that belongs to the loop.

A simple example to illustrate:

```
element.modify {addstart|10}
loop {('element' > "0" max=20)|end}
element.modify {calculate|1 -}
end_loop
```

This loop will subtract 1 from element until condition 'element' > "0" is false, which happens if it reaches 0. The value of *max=20* will not be reached.

4.6.4 The modify commands.

4.6.4.1 Replace

Performs a replacement of all occurrences of the string value of *expression-1* in the element to modify with that of *expression-2.* These expressions may contain *text, elements* and *scrubstrings* components (see 4.6 expression-1 and -2 components). Expression-1 may also contain indices if combined with a *type=char,word,sentence,paragraph* or *element* argument (see 4.6.1.4) or regular expressions with a *type=regex* argument.
Note: *In the latter case (regex) the replacement is selective (only the matched string on the position where it matches is replaced)!!*
Examples:
rating.modify {replace(null)|TODOS LOS PÚBLICOS|todos} , replaces the string TODOS LOS PÚBLICOS in element rating by the string *todos*.
rating.modify {replace(type=word)|2|NIÑOS} , replaces the third word with NIÑOS, result TODOS LOS NIÑOS
!! When replacing sentences (type=sentence) or paragraphs (type=paragraph) make sure to add the sentence separator (.) or the paragraph separator (\n \r or \n\r) to *expression-2*.

4.6.4.2 Remove

The command *remove* comes in three variants depending on the argument *type:*

- Without argument *type* or with *type=string,* it removes all occurrences of the string value of *expression-1* from the element to modify. As with the command *replace,* the *expression-1 m*ay contain *text, elements* and *scrubstrings* components.
  Example:
  title.modify {remove(notnull type=string)|: 'subtitle'} * removes the value of element subtitle in title after the colon : , which is also removed.
  Suppose {single|<span id=programmeheading|: ||
} is the scrubstring for the subtitle element, the next gives the same result:
  title.modify {remove(notnull)|: '{single|<span id=programmeheading|: ||
}'}
- With *expression-1* containing indices, combined with argument *type=char* or *word* or *sentence* or *element.* In this case the part of the element, determined by the *indices* will be removed. (see 4.6.1.4)
- With *expression_1* containing regular expressions (see 4.6.1.5) and *type=regex*.

4.6.4.3 Substring

The command *substring* extracts parts of an element determined by the *indices* in expression-1. The result is the opposite of *remove* when this is used with indices. Command *substring* only works with *expression-1* containing indices, the argument type with one of the values *char, word, sentence* or *element* is required (see 4.6.1.4) or *expression-1* containing regular expressions together with *type=regex* (see 4.6.1.5)
Example:
rating.modify {substring(type=word)|0 1} , replaces the rating value by the value of its first word.

4.6.4.4 Addstart and Addend

These commands simply add the result of *expression-1* to the *element-to-modify.* With these commands indices in *expression-1* are not supported.

4.6.4.5 Calculate

This command allows simple arithmetic calculations. Supported are + (add) - (subtract) * (multiply) / (divide). Furthermore four special calculations are supported; # (count, see 4.6.4.5.1), @ (index-of, see 4.6.4.5.2), date and time calculations (see 4.6.4.5.3) and bitwise calculations (see 4.6.4.5.4)
Its syntax is based on RPN (Reverse Polish Notation), which differs from the standard *a + b* and uses *a b +* . Its advantage is that it avoids complex syntax like *(a + b) * c* which cannot be expressed without () in the standard way. In RPN it is simply *a b + c **

However, because it is thought that more complex calculations will seldom be necessary only a simplified version of RPN is

implemented. Like the standard *(a + b) * c / (d - e)* would be *a b + c * d e - /* in full RPN. Here we must do that in three steps : (step-1) *a b + c ** then (step-2) *d e* - then (step-3) *result-1 result-2 /*

The complete syntax of calculations :

Element.modify {calculate (optional arguments)|RPN expression}
Element.modify {calculate (optional arguments)|'element' RPN expression}

It can also be used without any RPN expression, in that case the element value is only converted to a numeric value in the format specified by the *format* argument:

Element.modify {calculate (optional arguments)}

A few examples :
temp_1.modify {calculate(format=F2)|'temp_1' 240 /}
Divides temp_1 by 240 and assigns the result back to temp_1. If temp_1 is not a numeric string, its value will be zero. If it contains numeric string(s), its value will be the value of first numeric string in it. For example suppose temp_1 has the value *width=576px ,* it will be converted into 576 and the result will be 2.40
In this first example the element to modify temp_1 is the same as the element from which the value is used. In that case the following is the same:
temp_1.modify {calculate(format=F2)|240 /}
temp_1.modify {calculate(not "0" format=F2)|2 +} Adds 2 to temp_1 if temp_1 is not "0". Uses the (pre)conditional expression not "0" , see 4.6.2

index_start.modify {calculate(format=time)|'previous_start' 'index_temp_1'+ 'previous_index_temp_2'+} Use of the previous_start and previous_index_temp_2 elements . In it, the value of the 'same' element is stored of the 'previous' show. (see 4.5.1 , 4.5.2 and APPENDIX C). Here index_start is calculated as the previous_start added by the value of index_temp_1 and the value of previous_temp_1.

Suppose the start time is given in any of the three supported numerical values of the *format=time* argument (see 4.6 arguments *format)*
index_start.modify {calculate(format=time)} which is the same as
index_start.modify {calculate(format=time)|1 *} will convert the element value in the hh:mm time format.

4.6.4.5.1 # Count:

It will return the number of occurrences that a certain string is contained in an element.
Count comes in two variants:

1. *Occurrence*. Without argument *type* (or with *type=string):*
   It will return the number of occurrences that a certain string is contained in an element.
   The syntax:

   element.modify{calculate(optional-arguments)|'other-element' string #} or
   element.modify{calculate(optional-arguments)|string #}

   - 'other-element' : the element in which the number of occurrences of "string" is counted. If 'other-element' is omitted the element to modify is evaluated for the occurrence of "string".
   - string : if entered as string value, like "; " it must be enclosed by "" to allow spaces in it. It can also be entered as 'element' , enclosed by '', like 'title', in which case the number of occurrences of the value of that element will be counted.
   - # : the operant for count.

   Example:
   starrating.modify {calculate(format=F0)|"*" #} This will count the number of * characters in starrating and assign that value to it in the F0 format (0 decimal digits). Suppose starrating is ***, then after this operation it will become 3.

2. *Length*: With argument *type* values *char, word, sentence, paragraph* or *element.* Returns the *length* of the *element.*
   The syntax:

   element.modify{calculate(type=xx optional-arguments)|#} or
   element.modify{calculate(type=xx optional-arguments)|'other-element' #}

- argument *type* : See 4.6, arguments.
If *type=char*, the length returned is the number of *characters* in *element* or *other-element.* Similarly, if *type=word, sentence* or *element* length is the number of *words, sentences* and *element values* respectively.
- optional-arguments: An obvious one here is *format.* (see 4.6 arguments)

4.6.4.5.2 @ Index-of:

This will return the starting position (index) of a certain string contained in an element. The result is 'index based' (starting with 0) The syntax:

element.modify{calculate(optional-arguments)|'other-element' string @} or
element.modify {calculate(optional-arguments)|string @}

- *'other-element'* : the element in which start location of "string" is determined. If 'other-element' is omitted the element to modify is evaluated for the location of "string".
- *string* : if entered as string value, like "; " it must be enclosed by "" to allow spaces in it. It can also be entered as 'element' , enclosed by '', like 'title', in which case the start location of the value of that element will be returned.
- *@* the operant for the index-of . If "string" occurs more than once it will return the start position of the first occurrence. If prefixed by a minus-sign, like -@ , the start position of last occurrence will be returned.
- (optional) argument *type* : See 4.6, arguments.
It specifies the index-base. Possible values are: *type=string* (default, the result is returned as string position), *type=char* (the result is returned as character positions), *type=word* (the result is returned as word positions), *type=sentence* (the result is returned as sentence positions), *type=paragraph* (the result is returned as paragraph positions) and *type=element* (the result is returned as element positions)
- Note: If the "string" doesn't occur in the element, -1 will be returned. Also, note that with types *word*, *sentence* and *element,* if in a word, sentence or element, the "string" is contained, the index position of it is returned.

Example: an element with value "the quick brown fox" and a "string" with value "own" . If :
type=char : result = 12
type=word : result = 2 (from the word : brown)
type=sentence : result = 0 (this sentence contains string "own")
type=element : result = 0 (this element has only one value which contains "own")

4.6.4.5.3 Date and time calculations

- With Date and Time calculations it is possible to add of subtract timespan values from date, time or timespan values.
- It can also be used to convert to - and format date, time and timespan values. If the input string is — or contains a numeric value it automatically converts it to a date, time or timespan in the specified or default format. (see also further down in this section)
- It will also automatically convert five types of numeric input values:
  - Decimal day-time values, like 16.35 will be converted into 16:21.
  - Decimal timespan values, like 16.35 will be converted into 16:8:24 days or 16:21 hours
  - Integer date values in VBA day-number format as used in MS-Office
    E.g. 40787 will be converted to 2011/09/01
  - Integer date values in UNIX date format (Seconds counting from
    01/01/1970). E.g. 1314866400 will be converted into 8:40 or 2011/09/01
  - Integer date values in JavaScript date format (1ms units counting from
    01/01/1970). E.g. 1314866400000 will be converted into 8:40 or 2011/09/01
  - Integer date values in .NET ticks format (100ns units counting from
    01/01/0001). E.g. 634504632000000000 will be converted into 8:40 or 2011/09/01

Its syntax:

element.modify {calculate(opt.args. format=time/date/timespan)|timespan +/-} or
element.modify {calculate(opt.args. format=time/date/timespan)|'element' timespan +/-} or
element.modify {calculate(opt.args. format=time/date/timespan)} or
element.modify {calculate(opt.args. format=time/date/timespan)|'element'}

or with the timespan in an element:

element.modify {calculate(opt.args. format=time/date/timespan)|'element' 'element' +/-}

- *timespan* (optional): The timespan to add or subtract. If format=time specify *hours:minutes*, if format=date specify *days:hours:minutes* or *days:hours.* If specified without timespan and +/- operator, the result is the date - or time formatted value of the input value. (See 4.6 *arguments, format* for details about date, time and timespan formats and date-time format strings)
  In the place of this timespan an element with the value and format of a timespan (as above) can be used if enclosed by ', like in the last syntax.
- +/- operators
- *'element'* (optional): Contains the input value. If omitted the input value is taken from the element to modify.
- *'element'* can also be one of the date/time read-only elements '*urldate*', '*now*' or '*showdate*' (see APPENDIX D, Read-Only elements). Its expanded value will be formatted conform the format argument value.

Examples:

element.modify {calculate(format=time)|2:15 +} gives the following results:
If element = 16:20 —-> 18:35
If element = 6.5 —-> 08:45 (the numeric value 6.5 is first converted to 6:30)
If element = 23.25 —-> 01:30
element.modify {calculate(format=time,HH:mm)} conversion:
If element = 12.33 —-> 12:20
element.modify {calculate(format=date,yyyy/MM/d H:mm)|1:5:30 -} gives the following results:
If element = 2011/11/15 9:55 —-> 2011/11/14 4:25
If element = 1314866400 —-> 2011/08/31 3:10 (the numeric UNIX date value 1314866400 is first converted to 2011/09/01 8:40)
element.modify {calculate(format=date,unix)}
If element = 2011/11/15 9:55 —-> 1321350900
element.modify {calculate(format=timespan,days/hours)|1:17 +}
If element = 7.23 —-> 8:22:31 days , —-> 8:30 hours
If element = 2:50, —-> 5:19:0 days , —-> 4:7 hours
element.modify {calculate(format=timespan,days/hours)}
If element = 7.23 —-> 7:5:31 days, —-> 7:13 hours

Another syntax that might come in handy by occasion, is when the *'element'* containing the input data is replaced by a constant. This must be done by adding '>> ' (two forwards arrows and a space) to the constant, like this:
element.modify {calculate(format=time)|3:22>> 3:12 +} result —-> 6:34 or
element.modify {calculate(format=timespan,days)|16.35>> } result —-> 16:8:24

A practical example:
This concerns a site the grabs more than one day of index pages at once. For that it requires to specify the start and stop date. Calculating and formatting this stop time can be done as follows:

1. Get the config timespan value and add 1 day because config_timespan_days is 0 based (see 4.5.3 for more info about the special element index_variable_element)
   index_variable_element.modify {calculate(format=F1)|'config_timespan_days' 1 +}
2. convert to the proper timespan string required to add to the start date , urldate
   index_variable_element.modify {calculate(format=timespan,days)}
3. get the start date from urldate and format as required
   index_temp_1.modify {calculate(format=date,yyyy-MM-dd)|'urldate'}
4. calculate and format the stop date by adding the number of days from 'index_variabe_element'
   index_temp_2.modify {calculate(format=date,yyyy-MM-dd)|'urldate' 'index_variable_element' +}

4.6.4.5.4 Bitwise Calculations

The program supports the most common operators for this type of calculations : *and*, or, xor and *not.*
Examples:
Assume *element* has the value 187
element.modify {calculate(format=F0)|32 and} * result element=32

element.modify {calculate(format=F0)|4 or} * result element=191
element.modify {calculate(format=F0)|85 xor} * result element=238
element.modify {calculate(format=F0)|not} * result element=68
It is also allowed , as with most other operations, to specify the source and target elements separatly
target_element.modify {calculate(format=F0)|'element' 4 or} * result target_element=191
All relevant optional arguments like debug and conditionals are allowed.

4.6.4.6 Cleanup

This can be useful to tidy-up the result of a scrubbed element. It:

- tries to remove remaining html tags. (see also the argument *tags=* further down this section)
- replaces newline \n and tabs \t characters by a space.
- removes carriage returns.
- replaces multiple spaces by single spaces
- removes leading and trailing spaces
- removes illegal xml characters.
- restores Unicode character sequences like \\u00e6 with the actual chars
- performs optional upper– and lower case conversions depending on the *style* argument.

Note that it is allowed to add newline \n and tabs \t to elements with the addstart, addend and replace command. If a clean-up is executed after this is done, they will be removed again. Cleanup should be executed before these operations in such cases. Its syntax:

Element.modify {cleanup(optional arguments)}

- optional argument: *cleanup* has its own dedicated arguments *style, removeduplicates* and *tags.* (see 4.6, arguments). The *style* argument can be added to specify the required style of the cleanup result. Possible values are *style=sentence, style=name, style=upper* (convert to UPPERCASE) and *style=lower* (convert to lowercase)

4.6.4.6.1 Cleanup with argument *removeduplicates*

To remove duplicate members of multivalue elements. Its syntax:

Element.modify {cleanup(removeduplicates)} or
Element.modify {cleanup(removeduplicates=type)} or
Element.modify {cleanup(removeduplicates=type link=linked-elements)} or
Element.modify {cleanup(removeduplicates=type link=linked-elements span=xx)}

By default two (or more) elements are defined as duplicate if, when compared, the resulting matching factor is higher than the *titlematchfactor* (as described in 4.3) specified in the SiteIni.

- type, optional. Specifies the algorithm and (optional) the matching factor that is used to determine duplicates. Possible values are *equal (*default)*, title* and *name . Equal* doesn't use any special measures apart from the *matchingfactor. Title* uses a case insensitive comparison excluding certain abbreviations that is also used to compare *index_title* with the *xmltv title* as part of the incremental update process (see 4.5.1, index_title). *Name* uses a special comparison method to compare names. This can be useful to remove duplicates in credit elements such as *actor.* It finds duplicates like John Doe and J. Doe. Optionally, together with *type* , a different matching factor than the default, can be specified. E.g. *Removeduplicates=name,50* or *removeduplicates=equal,70* etc.
- span , optional. Default: span=all. Specifies how far from each other in the input array the duplicates are accepted as duplicates. E.g. if span=1 only duplicates next to each other are accepted. This helps to remove duplicates from index_showsplit that resulted from index pages overlaps. Without this in some cases also shows that happen daily on the same time will be removed.
- link, optional. Specifies another multivalue element from which its members must be removed on the same position as the duplicates found in the *element.* A typical example is the linked elements *index_site_id* and *index_site_channel.* E.g. : index_site_id.modify {cleanup(removeduplicates=equal,100 link="index_site_channel")}

4.6.4.6.2 Cleanup with argument *tags.*

Without this argument *cleanup* removes strings enclosed by < and > of less than 15 characters. A more complete, programmable removal of 'tag like' string components in the element can be achieved using the argument *tags.* Its syntax:

Element.modify {cleanup(tags="start-string""end-string")}

- start-string . The string (or a single character) which defines the start of the 'tag' to be removed.
- end-string . The string (or a single character) which defines the end of the 'tag' to be removed.

The removed string includes start– and end-string.
Examples:
description.modify {cleanup(tags="<"">")} The simplest form, removes everything between *<* and *>*
description.modify {cleanup(tags="<a class""")} Removes everything between *<a class* and **
description.modify {cleanup(tags="\"http://""\" ."")} Removes everything between *"http://* and *" .*
A further option is to remove strings at the beginning or end of the element. For strings at the beginning use *tags="/=string*" and for at the end *tags=*"string=/"
Example:
description.modify {cleanup(tags="/=\"")} removes a " at the beginning of the description.

4.6.4.7 Clear

If it is required to clear the content of an element one is inclined to use remove, like this:
element-A.modify {remove|'element-A'}
This works for single value elements but not for a multi value one, which is a bit difficult to understand. The reason is that *remove*, without a type specification or with *type=string,* which is default, tries to locate the expanded string 'element-A' in each of the elements of element_A. As explained in 4.6.1.3, expanded multi value element values include the value of each of the elements it contains separated by the standard internal element separator | . It is obvious that it fails to locate such an expanded value in each of the elements of element_A.
To clear the content of multi value elements (and also single value elements!) one can use :
element-A.modify {remove(type=element)|'element-A' 0} or in short
element-A.modify {remove(type=element)|0}
This removes the elements of element-A , regardless their content, starting from the first (index 0) to the last (because that's default if no length is specified) (see also 4.6.1.4 Expression-1 with indices).
Because the complication to understand the scrubstring element-A.modify {remove(type=element)|0} it is also possible to simply use :

element-A.modify {clear}

The program automatically substites the command *clear* by *remove(type=element)|0*

4.6.4.8 Select

Preconditional arguments (see 4.6.2.1) offer a way to select an element with the operators = ~ But that may be simple for a single element but to select certain members from a multi value element involves to step through all the members in a loop and examining each member individually. This is not only time consuming but also requires a lot of lines in the SiteIni.
The command *select* makes this a lot easier and faster. It can be applied directly to multi value elements. Its syntax:

Element.modify {select(optional args)|string operator}

- string : The string for which the members of element are to be selected.
- operator : The comparison operator. Must be one of the following:
  - = string and member of element must fully match, case insensitive
  - == string and member of element must fully match, case sensitive
  - ~ member of element must contain string, case insensitive
  - ~~ member of element must contain string, case sensitive
  - /= member of element must start with string, case insensitive
  - /== member of element must start with string, case sensitive
  - =/ member of element must end with string, case insensitive
  - ==/ member of element must end with string, case sensitive

?title string and member of element must match following the titlematch algorithm and using the titlematchfactor as deciding factor (see also .6.4.6.1 type for more details about this algorithm)

?name string same as ?title using the namematch algorithm (also described in 4.6.4.6.1)

WARNING! Unlike other commands the following is not supported:
Element.modify {select(optional args)|'other-element' string operator}

4.6.4.9 Sort

An easy and fast way to sort the members of multi value elements by its value or a part of it. This command must always be accompanied by a scrub string and/or an operation to define the value of the special element *sort_by* (see APPENDIX D). Its syntax:

Element-to-sort.modify {sort(direction,for)} and
sort_by.scrub {scrubstring with argument (target="element-to-sort")} and/or
sort_by.modify {operation with argument (target="element-to-sort")}

- *direction* : Must be *ascending* or *descending*
- *for* : Must be *string* or *integer.*

  The sorting will be carried out using the value of *sort_by* , if properly linked to the element to sort with the argument *target= ,* using either a string-order if *for* is *string* or a integer-number-order if *for* is *integer.* In the latter case, the program will attempt to convert the value of *sort_by* to an integer. If that fails, the sorting will fail with a warning.

Example:
index_showsplit.modify {sort(ascending,string)}
sort_by.scrub {single(target="index_showsplit")|<activation_datetime>||</activation_datetime>|</activation_datetime>}
sort_by.modify {calculate(target="index_showsplit" format=date,unix)}

4.6.5 Examples of operations

description.modify {addstart("")|no details} adds - no details - to an empty description
description.modify {addstart(null)|no details} same as above, adds - no details - to an empty description
subtitle.modify {addstart(not "")|Episode: } adds -- Episode: -- before the subtitle, but only if subtitle wasn't empty before the action.
rating.modify {replace("")|nine|9} replaces the word 'nine' by the number 9, also if the word 'nine' is the whole rating
description.modify {replace(not "")|Afl.: 'subtitle'.| This episode:} replaces the subtitle listing like - Afl.:Heads Up. - in the description by -- This episode: -- but only if the action doesn't replace the whole description.
ratingicon.modify {addstart("")|'rating'.png} adds a ratingicon if the site doesn't list one.

As an example of the use of a scrubstring in string-1, consider the following html:

* Amerikaanse (USA) Drama uit 1995 van Taylor Hackford. Met: Kathy Bates, Jennifer Jason Leigh, Judy Parfitt, Christopher Plummer e.a. Huishoudster Dolores wordt beschuldigd van de moord op haar vervelende en veeleisende werkgeefster, bij wie ze al jarenlang in dienst was. Door deze gebeurtenis wordt ook de dood van haar man, twintig jaar geleden, weer opgerakeld en rechercheur John Macky is vastbesloten Dolores dit keer wel voor moord achter slot en grendel te krijgen. Haar dochter Selena, een succesvolle journaliste in New York, keert voor de zaak terug naar haar geboorteplaats in het kille Maine, waar ze gelijk weer met haar eigen jeugd geconfronteerd wordt. *
<table style="width: 60%;">
<tr><th width="65">Genre</th><td>Film</td></tr><tr><th>Acteur</th><td>Kathy Bates, Jennifer Jason Leigh, Judy Parfitt, Christopher Plummer</td></tr>
<tr><th>Regisseur</th><td>Taylor Hackford</td></tr>
</table>

This site lists the actors double, in the description after - Met: - and later following <th>Acteur .
To scrub the description and the actor we use:
description.scrub {single| || |<table}
actor.scrub {single(separator=","|<th>Acteur</th><td>||</td></tr>}
That leaves use with a description that contains all the actors which isn't perfect. However they can be removed with the following:
description.modify{remove(null)|Met: '{single| |Met:|e.a.|<table}' e.a.}

We cannot use the element actor in string-1 as in

description.modify{remove(null)|Met: 'actor' e.a.} because actor is not a single value xmltv element anymore due to the use of the argument — separator="," - in the actor scrub specification.
We allow - null - to be sure that the actors listing is removed even if it is the whole description. We add the following to have at least something in the description:
description.modify {addstart(null)|No details}

An example with calculate and numeric conditional arguments:
Suppose the subtitle of a show is the first sentence in the description on the html detail page. So we use something like :
subtitle.scrub {single(separator=". " include=first)|. . . . . }
However not all shows have a subtitle, consequently the result can also contain just the first sentence of the description. To distinguish between subtitle and a normal sentence, count the words .. max 3 words is considered a subtitle (or at least most probable)
temp_1.modify {calculate(not "")|'subtitle' " " #} * count the spaces
subtitle.modify {remove('temp_1' > "2")|'subtitle'} * clear subtitle if more that 3 words
description.modify {remove('temp_1' < "3")|'subtitle'} * remove the subtitle from the description.

5. Special Procedures and Tricks

5.1 Special procedures

5.1.1 How to configure a SiteIni file for a site using the POST Http protocol

As a preparation for the development of a SiteIni using the POST method of a HttpWebRequest it is necessary to determine the required header content. There are numerous ways to do that, a simple one is to use the development tools of your internet browser. All respectable web browsers have such tools to inspect the traffic. For IE it can be found under *Tools*, select *Developer Tools (*F12), *Network* (Ctrl+4), *Enable Traffic* (F5). All traffic will be captured after this and can be inspected. It is essential to familiarize with this tool. With it the required request headers including the *postdata* content (in this tool called "Request Body") can be determined and must be copied to the header specifications as described in 4.4.1.1

5.1.2 How to configure a SiteIni file for a site using the POST_BACK Http protocol

First : read 4.4.1.1. Different from a 'regular' POST HttpWebRequest, the *postdata* which specifies the requested content to the server (site) is partly send to the client (in this case WG++) in response on a first request done using the GET method. Any following requests (e.g. for following days) use the POST method with *postdata* derived from the data received in response on the first GET request. WG++ follows a build in procedure when a POST_BACK request is started:

1. *Setup of a GET HttpWebRequest using the url_index as specified in the SiteIni.*
2. *If a valid response is received, a 'special' build-in scrub procedure (see below) is started to extract the required data to compose the required Postdata.*
3. *The program then issues the next HttpWebRequest using method POST with this postdata and the same url_index as in step 1. (So, in fact it grabs this first page twice, once to extract the postdata and a second time as part of the regular grabbing).*
4. *Any following request is done using the POST method as described above.*

Prior to designing the SiteIni entries, determine the necessary headers and postdata in the way described in 5.1.1. Match the postdata content with data found on the html page in response of the GET request. Tip: Locate the data that contains the string *VIEWSTATE*. Also Locate the possible variables and their format like channel , urldate and subpage. These variables must be added to the postdata header specification and not to the elements specified in the 'special scrub procedure'. (This procedure is only executed once, immediately after the first GET response, so will not be evaluated after the following POST responses if specified there)
The 'special' scrub procedure as mentioned in 2. must be specified in the SiteIni using these rules:

- *Use scope=urlindex e.g. within scope.range {(urlindex)|end} and end_scope*
- *Only the elements index-variable_element and the 6 available index_temp_1 to 6 are allowed.*
- *At the end of the procedure, the extracted data required for the following POST request must be placed in the element index_variable_element.*
- *two header specifications are required as a minimum:*
  url_index.headers {method=POST_BACK} to initiate this method and activate the special scrub
  url_index.headers {postdata= —- the required postdata —- }

An example:

- url_index with the channel variable as discovered in the variable part of the postdata:
  url_index{url()|http://etfarag.com/Programs/ChannelDisplay.aspx?ChannelID=|channel}
- the required urldate format:
  urldate.format {datestring|dd"%2F"MM"%2F"yyyy}
- the headers:
  url_index.headers {method=POST_BACK}
  *url_index.headers {accept=application/x-ms-application, image/jpeg, application/xaml+xml, image/gif, image/pjpeg, application/x-ms-xbap, */*}*
- the postdata containing the index_variable_element containing the data scrubbed from the
- GET response, added to it a variable part containing urldate:
  url_index.headers {postdata=__EVENTTARGET=ctl00%24MainContent%24ChannelDisplay2%24txtDate%24txtDate&__EVENTARGUMENT=&__LASTFOCUS=&__VIEWSTATE='index_variable_element'&ctl00%24Login1%24txtUserName=&ctl00%24Login1%24txtPassword=&ctl00%24Timezone1%24drpTimezone=60&ctl00%24Search1%24txtSearch=&ctl00%24MainContent%24ChannelDisplay2%24drpChannls='channel'&ctl00%24MainContent%24ChannelDisplay2%24txtDate%24txtDate='urldate'&ctl00%24MainContent%24ChannelDisplay2%24txtDateDown%24txtDate='urldate'&ctl00%24Register1%24txtName=&ctl00%24Register1%24txtPass=&ctl00%24Register1%24txtRePass=&ctl00%24Register1%24txtEmail=&ctl00%24Register1%24dtCtlBirthDate%24txtDate=&ctl00%24Register1%24ddlTimezone=-1&ctl00%24Register1%24txtMobile=&ctl00%24Register1%24ddlCountries=-1&ctl00%24Register1%24ddlLanguages=-1}
- The special scrub procedure to extract the post_back postdata:
  scope.range {(urlindex)|end}
- scrub the VIEWSTATE content
  index_variable_element.scrub {single|id="__VIEWSTATE"|value="|" />|" />}
- it appears that the next control chars must be entered by their html char code in the VIEWSTATE value (this could be site specific):
  index_variable_element.modify {replace|+|%2B}
  index_variable_element.modify {replace|/|%2F}
  index_variable_element.modify {replace|$|%24}
  index_variable_element.modify {replace|\||%7C}
  end_scope

5.1.3 How to configure a SiteIni file for a site using the SOAP http protocol

First : read 4.4.1.1. Although, like the POST and the POST_BACK method, SOAP also uses request data to be send to the server. This method uses a XML file 'SOAPENVELOPE' which is automatically generated by the program after being filled with the content of the postdata header from the SiteIni.

Unfortunately the content of this data cannot be figured out with the tools used for the POST and the POST_BACK method (see 5.1.1 and 5.1.2). Instead a dedicated 'sourceforge' program 'soapui' can be used to configure a SOAP request. (http://sourceforge.net/projects/soapui/files/soapui/4.5.2/)
An example of the use of this program is can be read in Example-Use-Of-SoapUi.pdf available @ http://www.webgrabplus.com/sites/default/files/download/documentation/Set%20of%20help%20files/help-files.zip

With de data collected that way , the SiteIni can be constructed. As example the following lines from schedulesdirect.org.ini:

url_index {url|http://webservices.schedulesdirect.tmsdatadirect.com/schedulesdirect/tvlistings/xtvdService}
url_index.headers {methode=SOAP}
* The headers, notice the username and password as required by this site
url_index.headers {customheader=SOAPAction=urn:TMSWebServices:xtvdWebService#download}
url_index.headers {customheader=Accept-Encoding=gzip,deflate}
url_index.headers {credentials=ENTER_USERNAME,ENTER_PASSWORD}
url_index.headers {accept=text/xml|contenttype=text/xml;charset="utf-8"}
url_index.headers {postdata='index_variable_element'}
scope.range {(urlindex)|end}
*
* timespan calculation to enable to add the requested timespan from the config

* add 1 day because config_timespan_days is 0 based:
index_variable_element.modify {calculate(format=F1)|'config_timespan_days' 1 +} index_variable_element.modify {calculate (format=timespan,hours)} * convert to the proper timespan string required for the date calculation in index_temp_2
**
index_temp_1.modify {calculate(format=date,yyyy-MM-dd)|'urldate'}
index_temp_2.modify {calculate(format=date,yyyy-MM-dd)|'urldate' 'index_variable_element' +}
*index_variable_element.modify {clear} * clear the timespan value*
index_variable_element.modify {addstart()|<SOAP-ENV:Envelope xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/" xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding/" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001/XMLSchema"><SOAP-ENV:Body><m:download xmlns:m="urn:TMSWebServices" SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/"><startTime xsi:type="xsd:dateTime">'index_temp_1'T00:00:00Z</startTime><endTime xsi:type="xsd:dateTime">'index_temp_2'T00:00:00Z</endTime></m:download></SOAP-ENV:Body></SOAP-ENV:Envelope>}
end_scope

5.2 Tricks

- Force a show update like this: title.modify{addend(~ "NOS WK Voetbal")|(!)}
By addition of (!) (or also (?)) to the title WebGrab+Plus will update the show despite the update decision outcome. This can be useful for shows that could have last minute changes that are not apparent from the index show times and index title. To get this update scheduled for already existing shows in the xmltv file a one-time full update run is necessary (set the update attribute to - f - in the channel entry of the WebGrab++.config.xml file for one run, like: <channel update="f" site="tvgids.nl" site_id="1" xmltv_id="NED1-tvgids">NED1</channel>)

- Avoid unnecessary show update:
If the index_title is different from the title on the show detail page and a lower setting of the title match factor is unacceptable (too low for reliable title comparison) try the following:
title.modify{replace(null)|Sterren 24|'index_title'}
The show in this example has - *Sterren.nl Extra* - as index_title and - *Sterren 24* - as show detail title, which is too much difference even for a title match factor of 50. With this we simply replace the title with the index_title for a show with title - *Sterren 24* - only.

- Full rating to Short rating

Sites normally list ratings like KIJKWIJZER ratings in a sentence like - *Afgeraden voor kinderen jonger dan 9 jaar* - of - *Let op met kinderen tot 9 jaar* - of - *drugs- en/of alcoholmisbruik* -

The ratingicon is normally listed as a link to a picture file like - *http://u.omroep.nl/gids/pics/icons/kijkwijzer/negen.png-* or - *http://u.omroep.nl/gids/pics/icons/kijkwijzer/groftaalgebruik.png-*

With the help of the modify operations they can be simplified easily (e.g. for site tvgids.nl):

rating.modify {replace(null)|Afgeraden voor kinderen jonger dan 6 jaar|6+}
rating.modify {replace(null)|Let op met kinderen tot 9 jaar|9+}
rating.modify {replace(null)|Afgeraden voor kinderen jonger dan 12 jaar|12+}
rating.modify {replace(null)|Niet voor personen tot 16 jaar|16+}
rating.modify {replace(null)|Grof taalgebruik|Grof}
rating.modify {replace(null)|Drugs- en/of alcoholmisbruik|Drugs}
ratingicon.modify {replace(null)|http://u.omroep.nl/gids/pics/icons/kijkwijzer/zes.png|6.png}
ratingicon.modify {replace(null)|http://u.omroep.nl/gids/pics/icons/kijkwijzer/negen.png|9.png}
ratingicon.modify {replace(null)|http://u.omroep.nl/gids/pics/icons/kijkwijzer/twaalf.png|12.png}ratingicon.modify {replace (null)|http://u.omroep.nl/gids/pics/icons/kijkwijzer/16.png|16.png}ratingicon.modify {replace(null)|http://u.omroep.nl/gids/pics/icons/kijkwijzer/seks.png|seks.png}ratingicon.modify {replace(null)|http://u.omroep.nl/gids/pics/icons/kijkwijzer/eng.png|angst.png}ratingicon.modify {replace(null)|http://u.omroep.nl/gids/pics/icons/kijkwijzer/geweld.png|geweld.png}
ratingicon.modify {replace(null)|http://u.omroep.nl/gids/pics/icons/kijkwijzer/groftaalgebruik.png|grof.png}
ratingicon.modify {replace(null)|http://u.omroep.nl/gids/pics/icons/kijkwijzer/discriminatie.png|discriminatie.png}
ratingicon.modify {replace(null)|http://u.omroep.nl/gids/pics/icons/kijkwijzer/drugs.png|drugs.png}

A set of ratingicon files for the Dutch 'KIJKWIJZER' ratingsystem with the filenames as used in this example is included in the WebGrab+Plus distribution.

- Some *exclude* and *include* tricks:

- Exclude elements with more than one word (sentence)

element.scrub {single (exclude=" ")|scrubstring}
This is very helpful to filter out (in general) one-word elements like category. A lot of sites use unsystematic html structures. Especially secondary elements like category can be mixed with other elements like title or subtitle behind the same bs es ee and bs values. This filter can help to separate them.

- Include a list of standard values

category.scrub {single (include="film""serie""documentary""sports")|scrubstring}
Another way to filter a category out of a mixed html scrubbed element. The list of strings to include should contain all the possible categories which occur in the html scrub.

- A combination of *include* and *exclude* to further refine the result.

Consider the following scrubstring:

category.scrub {single (include="film""serie""documentary""sports" exclude=" ")|scrubstring}
The include list allows to yield an element with the value - memories of a seriekiller - , which probably is a title and not a category. The exclude=" " removes this element value.

6. MDBIni file

6.1 Introduction

The MDB postprocessor, as shortly mentioned in 3.2, allows to add additional movies or series data grabbed from online movie and serie data-bases to the xmltv file created by the frontend WebGrab+Plus grabber. To achieve this it performs the following steps:

1. Select 'candidate' shows from the xmltv input file.
2. Match the selected show 'candidates' with shows in the online MDB in two steps:
   - A 'Primary search' with a general search site like BING, ASK, GOOGLE or directly in the MDB site if that supports search. This results in a number of possible show-id's for the next step:
   - Verify the results of the primary search in a MDB-site, like IMDb, until a 'match' is found.
3. Grab the MDB data of the matched show-id from the MDB site
4. Merge the grabbed MDB data with the epg data from existing xmltv file.

Due to the flexible programmable approach, much like the frontend grabber, it is possible, in principle, to grab this additional data from any of the existing online movie and serie data-bases 'MDB-sites' like IMDb.com, Allocine.com, TheTVDb.com etc. This is achieved with a MDBIni file, similar to the SiteIni file of the frontend grabber, in which all the MDB-site dependent settings and operations are specified.

The MDB postprocessor, like the frontend grabber, uses its own configuration file, MDB.config.xml in which the user can specify the location of relevant files, the selection and matching parameters and what, where and how to merge the grabbed MDB data with the existing xmltv file. (See 3.2 and http://www.webgrabplus.com/documentation/configuration-mdb/mdbconfigxml)

Besides this config file, it uses one or more MDBIni files, optimized for different MDB_sites or for using a different Primary search-sites or optimized for movie or series data grabbing. These MDBIni files use the same scrubstring and operations syntax as the SiteIni files with a few small exceptions and additions. Thus, all the commands and syntax specifications described in chapter 4 are also valid for these MDBIni files besides these small exceptions and additions. (see 6.3) It is obvious that this postprocessor has it own set of supported elements, different from the ones of the SiteIni files. (see 6.2)

6.2 MDB Elements

The following table lists all the supported MDB element names and the General MDB-site dependent settings.

Supported MDB Element names:

Element Name	source page	action: .url	.headers	.scub	.modify	Description
url_primarysearch		✓	✓		✓	The url of the primary search
url_mdb_p1 *upto* url_mdb_p8		✓	✓		✓	The url of the mdb-site data pages
show_id	primary			✓	✓	The show_id that the MDB-site uses as show reference
mdb_episode_id	p1 - p8			✓	✓	The episode_id of a series episode that the MDB-site uses as reference
mdb_episode	p1 - p8			✓	✓	The episode number, like seaon, episode, part
mdb_title	p1 - p8			✓	✓	The show title as present in the MDB-site
mdb_subtitle	p1 - p8			✓	✓	In case of a series episode, the episode title or just a show subtitle
mdb_description	p1 - p8			✓	✓	The show description as present in the MDB-site
mdb_starrating	p1 - p8			✓	✓	The MDB-site starrating
mdb_starratingvotes	p1 - p8			✓	✓	The number of viewer votes that contributed to the mdb_starrating
mdb_plot	p1 - p8			✓	✓	A short description of the show
mdb_commentsummery	p1 - p8			✓	✓	A selection of viewers 'ono line' comment summaries
mdb_review	p1 - p8			✓	✓	A selection of viewers reviews
mdb_actor	p1 - p8			✓	✓	A selection of actors present in the MDB-site of the show or serie
mdb_director	p1 - p8			✓	✓	A selection of directors present in the MDB-site of the show or serie
mdb_showicon	p1 - p8			✓	✓	The showicon as available in the MDB-site
mdb_productiondate	p1 - p8			✓	✓	The year of production of the show as given by the MDB-site
mdb_temp_1 *upto* mdb_temp_6	any			✓	✓	Usefull temporary elements in operations
mdb_variable_element	any			✓	✓	The MDB variant of index_variable_element
General MDB-site dependent settings : optional:						
url		The url of the 'home' page of the MDB-site				e.g. IMDb.com
culturenfo		The culture-info for the MDB-site				e.g. en-UK
charset		The charset in which the MDB-site page are coded				e.g. utf-8
matchfactor		A number that sets the accuracy of the string matching				e.g. 80
grabengine	✓	Selects which grabengine is used				e.g. internal (default) or wget
episodesystem	✓	A string that describes the value of the episode				xmltv_ns or onscreen
searchsite	✓	The primary search site used				e.g. bing

6.2.1 Variables in URL element values

- In *url_primarysearch* :
  - *'title'* : expands to the title of the show in the xmltv source file
  - *'credit'* : expands to the first director or if not available the first actor of the show in the xmltv file
  - *'productiondate'* : expands to the prouctiondate (element <date>) of the show in the xmltv file
- In *url_mdb_pn* :
  - *'mdb_show_id'* : expands to the show_id found with the primary search
  - *'mdb_episode_id'* : (series only) expands to the episode_id found with in the first MDB page

  * Note : Also recognised are *'show_id'* and *'episode_id'* , without the *mdb_* prefix

Examples of URL specifications in a MDBIni:

url_primarysearch {url(urlencode=1,2,3,4)|http://www.ask.com/web?&q=|imdb+|'title'|+|'credit'|&/NCR}

url_mdb_p1 {url|primary|http://www.imdb.com/title/tt|'mdb_show_id'|/}

*url_mdb_p2.modify {addstart|http://www.imdb.com/title/tt'mdb_episode_id'} * the episode detail page*

6.3 Differences between MBDIni and SiteIni syntax.

6.3.1 Element prefix.

In SiteIni's elements the prefix , like *index_ detail_* and *subdetail_* is used to specify the (html) source page from which the element content is to be scrubbed. Not so in a MDBIni, in these, all elements that get their data from any grabbed html MDB-site page have a standard *mdb_* prefix. The html source page from which the content is to be scrubbed is specified

before the sequence |bs|es|ee|be} (see 4.2.1.1) or before the regex specification (see 4.2.4.2) as follows:

Element.scrub {type(optional arguments)|*page*|bs|es|ee|be}

Element.scrub {regex(optional arguments)|*page*||regular expression||}

- *page ,* the (html) source page from which the data content is to be scrubbed.
  Possible values are :
  - *primary ,* the primary search page.
  - *p1 .. p8 ,* any one of the 8 possible MDB-Site grabbed pages
- *Type, bs, es, ee, be* and *arguments* : Same as in a SiteIni , see chaper 4
- *Regex, regular expression:* Same as in a SiteIni, see 4.2.4.2

6.3.2 Argument urlencode

The argument *urlencode=pos1,pos2,..,posn* allows to encode the resulting url string, it converts characters that are not allowed in a URL into character-entity equivalents. For example each space character will be converted to a plus character (+) and a plus character to %2b and more. This is required here because the variables *'title'* and *'credit'* often contain space and possibly other charaters that are not allowed in URL's. One can split the url specification into pieces, separated by the well known | character and use the *pos* values (0 based) to point to which of the pieces should be urlencoded.
Example:

url_primarysearch {url(urlencode=1,2,3,4)|http://www.ask.com/web?&q=|imdb+|'title'|+|'credit'|&/NCR}

- pos=1 *imdb+* urlencoded to *imdb%2b*
- pos=2 *'title'* e.g. expanded to *Take this waltz* urlencoded to *Take+this+waltz*
- pos=3 *+* urlencoded to *%2b*
- pos=4 *'credit'* e.g. expanded to *Tim Story* urlencoded to *Tim+Story*
- * Note : in type *url* scrubstrings the variables (here *'title'* and *'credit'*) must be placed between || (see 4.4.2) and therefore have their own pos (2 and 4) and cannot be combined with the others.

Result:

http://www.ask.com/web?&q=imdb%2bTake+this+waltz%2bTim+Story&/NCR

6.4 Series episode details

If the source xmltv file lists series shows of which the subtitle is the episode title, it is possible to obtain more episode details from a MDB-site that contains this data. (like *IMDb.com* and *thetvdb.com*). The procedure to do this is a little more complicated than that for a movie , which requires a dedicated *MDBIni for series*. The objective is to get the *mdb_episode_id* , only with that the episode details can be grabbed:

- Obviously , in mdb.config.xml, this dedicated *MDBIni for series* must be selected
  <site series="imdb.com.imdb.series" movies="imdb.com.ask,imdb.com.imdb"></site>
  And , also in mdb.config.xml , the subtitle is the required *mustmatch*
  <matchserie optional="" mustmatch="title,subtitle" minimum="2"></matchserie>
- In this *MDBIni for series* ,
  - Configure a primarysearch with *'title'* and *'credit'.* (Like the one in 6.3.1) and scrub the *show_id* candidates (the id of the series as a whole, not one particular episode)
  - With this *show_id* configure an *url_mdb* that results in a (html) page that contains a list of all the episodes of the series with this *show_id,* like this for IMDb.com:
    url_mdb_p1.modify {addstart|http://www.imdb.com/title/tt'mdb_show_id'/epdate}
  - Next, scrub all the episode titles in *mdb_subtitle.*
  - The program will now automatically start a matching routine that will select the one *mdb_subtitle* that matches the (xmltv) subtitle best, resulting in a single value *mdb_subtitle* with the value of the requested episode title !
  - Also, to get the required *mdb_episode_id,* from the same page with all the episodes listed, scrub all these episodes in a multi value mdb_temp element , and select the one which contains the single *mdb_subtitle* scrubbed in the previous step, like
    mdb_temp_1.scrub {multi|p1|<h3>Episodes Rated by Date</h3>|<td><a href="/title/tt|</tr>|<br style="clear:both;" />}
    mdb_temp_1.modify {select|'mdb_subtitle' ~} * select the one and only with the episode title

- Now , get the *mdb_episode_id* ,

mdb_episode_id.modify {substring(type=regex)|'mdb_temp_1' "(\d\{7\})/\">"}

- With this *mdb_episode_id* grab the episode details with url_mdb's like these for IMDb.com

*url_mdb_p2.modify {addstart|http://www.imdb.com/title/tt'mdb_episode_id'} * the episode detail page*

*url_mdb_p3.modify {addstart|http://www.imdb.com/title/tt'mdb_episode_id'/synopsis?ref_=tt_stry_pl} * the full synopsis*

*url_mdb_p4.modify {addstart|http://www.imdb.com/title/tt'mdb_episode_id'/fullcredits?ref_=tt_ql_1} *full cast and crew*

*url_mdb_p5.modify {addstart|http://www.imdb.com/title/tt'mdb_episode_id'/plotsummary?ref_=tt_ql_5} *plot summary*

*url_mdb_p6.modify {addstart|http://www.imdb.com/title/tt'mdb_episode_id'/reviews?ref_=tt_ql_7} *user reviews*

———-END———

APPENDIX A Feature list of the program

⇒ Runs in *Windows*, *Linux* and *OSX*

⇒ Can grab from *multiple sites*, programmable by user trough a *SiteIni* file.
As of June 2014 SiteIni files available for *219 TV-guide sites worldwide* in 55 countries
(see http://www.webgrabplus.com/epg-channels)

⇒ *Very fast* through *incremental* grabbing (only changed and new shows grabbed)

⇒ Ability to *import epg data* from (other source) xmltv files and *merge* that with that of the grabbed data.

⇒ *Programmable* through editing commands that enable *changing, filtering, adding, moving, removing (parts)* and *calculating* of the xmltv elements.

⇒ Support of *combi-channels*, channels that show programs from different source channels at specific periods of the day.

⇒ Support of *time-offset channels*, channels that only differ from another one through a timeshift.

⇒ Ability to grab from a *very wide range of epg structures* of the supported html pages. E.g. *single -day, multi-day, multi-page single-day, channel-fragmented single-day* and many other variants.

⇒ Supports grabbing from *compressed* feeds (gzip and deflate) through build-in decompression.

⇒ Can extract xmltv elements from a very *wide range of webpage data formats* like *html, ftp, xml, xmltv, mxf, csv , json* and others.

⇒ Very *flexible url-builder* (that builds the url of the index-page) with support for *day-number, weekday-name, weekday-number, date-string, date-number, date-lists* and *sub-pages*.

⇒ Support for *Http* WebRequest methods *GET* and *POST*, *POST_BACK* and *SOAP* plus header specifications.

⇒ Support for *Ftp* WebRequest, including access credentials *username* and *password*.

⇒ Support of grabbing of *nearly all (25) xmltv* elements.

⇒ Support of grabbing in *all languages* (that can be represented in a standard character set), including the non alphabetic like Chinese, Russian, Greek, Japanese etc.

⇒ Can grab from *1, 2 or 3 web pages* (index - , detail - and subdetail page)

⇒ Automatic forward looking *DST* (daylight saving time) adaptions .

⇒ Integrated worldwide *TimeZones* database and their *DST rules.*

⇒ *Fair use of site resources* through user programmable delays between subsequent channels, index pages and detail pages.

⇒ Programmable *retry* and *time-out* settings for bad or slow internet connections.

⇒ Conforms to the 'ROBOTS exclusion standard' (http://www.robotstxt.org/wc/robots.html) through a screen warning.

⇒ Optional *MDB postprocessor* that automatically grabs additional data from *IMDb* and other online movie and serie databases.

⇒ Optional *REX postprocessor* that allows *re-allocation* and *merging* of xmltv elements

APPENDIX B Example config files:

WebGrab++.config.xml file

```
<?xml version="1.0"?>
<!-- Configuration file for WebGrab+Plus, the incremental Electronic-Program-Guide web grabber
by Jan van Straaten, June 2014
Version V1.1.1.54 -->

<settings>

<!-- filename
The path (required) + filename where the EPG-guide xml file is /will be located. It must include drive and folder. Like
C:\ProgramData\ServerCare\WebGrab\guide.xml
If the file already exist (from last run or from another xmltv source) it will read it and use what fits the requested output. In
that case the file will be updated. If no such file exist it will be created.
Change the following to your own needs   -->

<filename>C:\ProgramData\ServerCare\WebGrab\guide.xml</filename>

<!--   modes:
d or debug    saves the output xmltv file in a file with -debug addition in the file name .
              The original xmltv file will be kept.
m or measure  measures the time for each updated show or new show added
n = nomark    disables the udate-type marking (n) (c) (g) (r) at the end of the description
v or verify   verifies the result following a channel update
w or wget     use wget as grab engine (can improve site recognition)
Note that modes can be added in one line, separated by comma's or spaces, or both. -->

<mode>m</mode>

<!-- postprocess:
Optional , specifies which of the available postprocesses should run.
syntax: <postprocess run="" grab="">processname</postprocess>

(optional) grab="yes" or "y" or "true" or "on" : grabs epg first (default)     ; "no" or "n" or "false" or "off" : skip epg grabbing
(optional) run="yes" or "y" or "true" or "on" : runs the postprocess (default) ; "no" or "n" or "false" or "off" : do not run post
process
processname: the process to run :
processname = mdb runs a build in movie database grabber (read / adapt  ...\mdb\mdb.confif.xml
processname = rex runs a postprocess that re-allocates xmltv elements (read / adapt  ...\rex\rex.config.xml)
examples:
  <postprocess run="on" grab="on">mdb</postprocess>  grabs first , then run mdb
  <postprocess>mdb</postprocess>  same as above (uses defaults for grab and run)
  <postprocess grab="no">rex</postprocess>  runs rex without grab (existing xmltv file)
-->
  <postprocess>mdb</postprocess>

<!-- proxy:
This setting is only required if your computer is connected to internet behind a proxy
specify proxy address as ip:port like <proxy>192.168.2.4:8080</proxy>
or as <proxy>automatic</proxy> which attempts to read the proxy address from your connection settings. If your proxy
requires a username and password, add them like
<proxy user="username" password="password">192.168.2.4:8080</proxy>   -->

<proxy>automatic</proxy>

<!-- user agent:
The user agent string that is sent to the tvguide website. Some sites require this.   Valid values are either <user-
agent>random</user-agent>, in which case the program generates a random string,   or any other string like <user-
agent>Mozilla/5.0 (Windows; U; MSIE 9.0; WIndows NT 9.0; en-US)</user-agent>-->
```

```
<user-agent>Mozilla/5.0 (Windows; U; MSIE 9.0; WIndows NT 9.0; en-US)</user-agent>

<!-- logging:
simply put 'on' in there to start logging, anything else will turn it off -->
<logging>on</logging>
<!-- credentials:
For sites that require login with username and password. Multiple credential for different sites allowed -->
<credentials user="username" password="password">site.com</credentials>

<!--retry
The most simple form of retry defines the amount of times the grabber engine should attempt to capture a web page before giving up and continuing with the next page, like <retry>4</retry>
It is also the place to specify delays between retries and the grabbing of html pages with the following attributes: timeout; the delay between retries (default is 10 sec), channel-delay; the delay between subsequent channels (default is 0), index-delay; the delay between the grabbing of index pages (default is 0), show-delay; the delay between the grabbing of detail show pages (default is 0). In the most complete version it will look like this:
<retry time-out="5" channel-delay="5" index-delay="1" show-delay="1">4</retry> -->

<retry time-out="5">4</retry>

<!--skip
It takes two values H,m  separated by a comma:
The first H : if a show takes more than H hours, it's either tellsell or other commercial fluff, or simply a mistake or error, we want to skip such shows.
The second m : if a show is less or equal than m minutes it is probably an announcement , in any case not a real show.
When entered as <skip></skip> the defaults are 12 hours, 1 minute. To disable this function enter <skip>noskip</skip> or just leave out this entry completely-->

<skip>13, 1</skip>

<!--timespan
The timespan for which shows will be grabbed.
It takes one or two values separated by a comma. The first is the number of days (including today) to download, note that 0 is today. The second (optional) is a time specified between 0:00 and 24:00 which will reduce the download to only the one show (per day) which is scheduled around the specified time. Any value between start time (including) and stop time will do
This -one-show-only mode is helpful if a SiteIni file needs to be debugged-->

<timespan>0</timespan>

<!-- update mode
i or incremental     only updates of changes , gabs, repairs and new shows
l or light           forces update of today and new shows, rest as incremental
s or smart           forces update of today and tomorrow and new shows, rest as light
f or full or force   forces full update

If one of these values is entered here it will apply to all channels selected for update
(see channel).  This value overrules the value of 'update' for in the individual channels
If no value is entered here the individual 'update' values from the channellist are taken -->

<update></update>

<!-- The channel-list :
Each channel to be grabbed has a separate entry in the list, the most common form is:
<channel update=.. site=.. site_id=.. xmltv_id=..  >display-name</channel>
Besides this form, there is a possibility to specify special channels like 'combi-channels' and 'timeoffset-channels', see further down for more information-->
<!-- Channel list files :
The easiest way to compose this channel-list is to copy the required channels from the channel-list files which can be found in the SiteIni.Pack for nearly every supported tvguide site. -->
<!-- update :
The mode values here can be set for each channel differently if not overruled by the general update setting (see above).
```

Allowed values are as the same as the general update setting. Any other value will be ignored. If any of the allowed values of 'update' is entered, this channel will be updated , no value no update ! In that case the epg data of that channel will remain as it is. -->

<!-- site:
The website to be used to get the EPG from. The value entered here is the name of the .ini file that supplies the specific parameters for the site without .ini extension.
e.g tvgids.nl.ini becomes site="tvgids.nl" and gids.publiekeomroep.nl.ini becomes site="gids.publiekeomroep.nl".-->

<!-- site_id:
This is the number or text used by the site as reference to the correct html page for this channel. It is used by the program to compose the url for the shows for a channel. For nearly all sites supported by the program a channel-list file is provided in the SiteIni-pack. It list most of the available channels including this site_id -->

<!-- xmltv_id :
The xmltv_id can be any string that suits your needs, you will find it back as the "channel" in your xml file as in :
<programme start="20100218072500 +0200" stop="20100218075500 +0200" channel="RTL7-id"> -->

<!-- display-name:
This will be used in the xmltv file to give the channel's displayname. That is the name the epgprogram will use to display the channel. Give it any value you like. It is no problem if site_id , xmltv_id and display-name are equal -->

<!-- Important !

Be aware that all channels entered here will be included in the xmltv channel table even if no update is requested. This allows the update of individual channels without affecting the data of the others in the list. A channel not in this list will be removed from your xmltv listing together with all the show data of it if found there by WebGrab+Plus. (If you use WebGrab+Plus with a xmltv input file from another source, it will remove all data from channels not in this list and create an entry for new channels)
WebGrab+Plus uses the xmltv_id to identify a channel in an existing xmltv file.-->

<channel update="f" site="tvguide.co.uk" site_id="145" xmltv_id="Film4">Film4</channel>
<channel update="i" site="bfbs.com" site_id="8001" xmltv_id="BFBS">BFBS</channel>
<channel update="i" site="yelo.be" site_id="ned1" xmltv_id="NED1.wg">NED1</channel>
<channel update="" site="sincroguia.tv" site_id="18" xmltv_id="LA1">LA1</channel>
<channel update="" site="laguiatv.com" site_id="Tele+5" xmltv_id="Tele5">Tele5</channel>
<channel update="i" site="directv.com" site_id="554" xmltv_id="TMCeHD(r)">MovieEastHDr</channel>
<channel update="i" site="tvgids.nl" site_id="1" xmltv_id="NED1">NED1</channel>

<!-- Timeoffset-channels. Many sites list channels that differ only from anoher through a time difference. Instaed of grabbing the epg separately it is posible to just copy and timeshift the 'source´channel with a special channel specification.
For that use the attributes same_as and offset as follows:

Example of timeoffset-channels :

<channel update="i" site="laguiatv.com" site_id="Canal +" xmltv_id="Canal +">Canal +</channel>
<channel same_as="Canal +" offset="2" xmltv_id="Canal + 2">Canal + 2</channel>

The source channel (here ="Canal +") must always be listed before the timeoffset-channel (here "Canal + 2") The offset can also be negative like offset="-1"

<!-- Combi-channels. With these one can combine parts several channels in combi-channel. These parts can consist of daytime periods or shows with certain subjects. Please refer to Combi-Channels-Guide.txt for more info. The aruments period, include/exclude and site_channel can be used to specify these 'combi-channels' See the separate guide how-->

Example of a combi-channel:

<channel update="i" site="tvgids.nl" site_id="40" site_channel="AT5" xmltv_id="CombiChannel_Id" period="00:00-06:00" >CombiChannel_Name</channel>
<channel update="i" site="gids.publiekeomroep.nl" site_id="67" site_channel="RTL8" xmltv_id="CombiChannel_Id" period="06:00-24:00" >CombiChannel_Name</channel>
<channel update="i" site="tvgids.upc.nl" site_id="Ered.+live+2" site_channel="EredivisieLive2"

mdb.config.xml file :

```
<?xml version="1.0"?>

<!-- Configuration file for the MDB (Movie Data Base) postprocessor of WebGrab+Plus
by Jan van Straaten, December 2011
WebGrab+Plus Version V1.1.0-->

<!--  Introduction:
This MDB postprocessor of WebGrab+Plus, which is available from Version 1.1.0 onwards, automatically adds MDB (eg IMDb) data to the xmltv file created by the basic WebGrab+Plus EPG frontend grabber.
To activate/de-activate this postprocess, use the <postprocess> setting in WebGrab++.config.xml

This postprocessor performs the following steps:
1. Select ('candidate' shows from the xmltv input file)
      see <selectmovie> and <selectserie> settings.

2. Match (the selected show 'candidates' with shows in the online MDB (e.g. IMDb.com))
      see <matchmovie> and <matchserie> setting.

3. Grab (the MDB data) by default the following data is grabbed :
      (original show-) title, starrating, plot, description, commentsummaries and reviews

4. Merge (the grabbed MDB data with the epg data from existing xmltv file)
      see allocation and presentation.

The resulting xmltv output file (see xmltv file , <filename>) must be different from the xmltv input file . (changing that would disturb the incremental nature of the epg grabbing)

Matching the selected shows is done in two steps:

2.1 Primary search in a general search site like BING, ASK or YAHOO
      this results in a number of possible show-id's for the next step:

2.2 Verify the results of the primary search in a MDB site like IMDb
      each of the show-id's from step 2.1 is examed for a match with the <matchmovie> and <matchserie> setting.

Similar to the function of the SiteIni's in the epg grabbing all site dependent settings are stored in mdbini files.
    see mdbini files.
The Match and Grab results can be saved in a mdb data file. This speeds up the process.
      see local MDB data file.

This file (mdb.config.xml), the mdbini files (e.g imdb.com.ask.ini) and the mdbdata file (mdb.xml) are stored in the MDB postprocess home folder C:\ProgramData\ServerCare\WebGrab\MDB

-->
<settings>

<!--mdbini files:
mdb site(s) to use, must correspond with an ini file, e.g. if imdb.es there must be an imdb.es.ini.
If a second site is entered here, it will be used as a 'second chance' if the first doesn't find a match for a certain show.
examples :
<site>imdb.com/site>-->

<site>imdb.com.ask, imdb.com.bing</site>

<!--xmltv file : The xmltv target file in which the mdb data will be merged with the grabbed EPG.
Because of the incremental nature of the grabbing process this file must be different (name and/or path) from the target file of the grabbing as specified in WebGrab++.Config.xml <filename> !!

If omitted here or if by mistake the same file is specified , the file path will be changed to
C:\ProgramData\ServerCare\WebGrab\mdb\ -->

<filename>C:\ProgramData\ServerCare\WebGrab\mdb\guide.xml</filename>

<!--local MDB data file
```

The file that stores the mdb data locally with the intention to re-use already grabbed data which will speed up the grabbing of the mdb data.
If not specified no MDB data file will be used.
- update ; determines how the local MDB database file is updated
    update="" , left blank , will not be updated
    update="i" , incremental, only the selected shows will be saved in the local MDB data file
    update="f" , all shows will be kept and new shows added. This is the prefered update mode.

    (Over time this MDB data file could grow to an unpractical size with update="f". Unpractical if the time to match a selected show in this file exceeds the time to do the same online). -->

<ldbfilename update="f">C:\ProgramData\ServerCare\WebGrab\mdb\mdb.xml</ldbfilename>

<!--Selection :
selectmovie and/or selectserie: the imdb postprocessor selects shows from the xmltv file for which imdb data will be attempted to optain based on these two selection settings.
- duration="45" ; minumum duration is 45 minutes
- contains="film,thriller,movie" ; the epg data must contain at least these words or any other. This also allows to select single shows! Other example: contains="Kill the Irishman", will select shows that contains this sentence.
- musthave="title" ; obviously the epg show must have a title, if omitted the value is title, other additional musthave xmltv elements can be entered here.
- optional="productiondate,actor,director" ; specifies which xmltv elements will be added to the selection if available.
- minimum="2" ; specifies how many of the musthave + optional elements must be available for a show to be selected
- addif="subtitle,titleoriginal" ; additional xmltv elements if available on top of the minimum, not yet implemented!-->
<selectmovie duration="55" minumum="3" musthave="title" contains=" " optional="productiondate,actor,director"/>
<selectserie duration="25" minumum="3" musthave="title" contains="serie,soap,thriller,comedy,drama" optional="productiondate,actor,director"/>

<!--match , compare the epg and mdb values
- mustmatch ; default title , only possibly added by subtitle
- optional ; other elements that can be added to compare are: productiondate,actor,director
- minimum ; how many of the above needs to match-->
<matchmovie mustmatch="title" optional="productiondate,actor,director" minimum="2"/>
<matchserie mustmatch="title" optional="productiondate,actor,director" minimum="2"/>

<!--Allocation and presentation of mdb elements in the xmltv target file
This MDB-postprocessor makes use of the REX-postprocessor to allocate the mdb elements in the xmltv target. Please read the detailed explanation in rex.config.xml for information about the background of the specification syntax.

<![CDATA[
Here only the summary of it:
1. Syntax
  - the content of the xmltv-target elements can be specified by means of a mixture of text and element-values.
  - the element-values must be entered by their element-name enclosed by ''
  - multiple value elements (like actor) will be converted to single value elements if the xmltv-target element is a single value element, like <desc>. The individual values will be listed with a (standard WG++ internal element separator) | as separator unless another separator is specified as follows:
'element-name(separator-string)' e.g. 'actor(,)'
  - text and element-names can be linked together by enclosing them by {}. This will ensure that, when the element in it is empty, everything between the {} is ignored. E.g. {\nProduced in : ('productiondate')}
  - the text in the xmltv-target elements may contain the following simple formatting :
    - \n or \r to force a newline
    - \t to add a tab

2. The allowed xmltv-target elements (the ones in the target file specified above) are :

  <title> (= special case : if the first mdb-title, which is the original showtitle, differs from the xmltv title it can be added to xmltv as extra 'original' title.)

```
  <sub-title>
  <desc>
  <date> = the xmltv element name containing the productiondate
  <star-rating>
  <review> (=optional new xmltv element)
  <director> e.g to add /substitute the (additional?) mdb-director
  <actor> e.g to add /substitute the (additional?) mdb-actor

  - IMPORTANT! : any of the above listed xmltv-target elements that is specified in this allocation specification, replaces the existing xmltv element and its content!

3. Supported element-names (from the existing xmltv listing, name definitions as in Appendix D) :

  - 'title' 'description' 'starrating' 'subtitle' 'productiondate' 'category' 'director' 'actor' 'presenter' 'writer' 'composer' 'producer' 'rating' 'episode' 'review'  'subtitles' 'premiere' previously-shown' 'aspect' 'quality'

4. Supported MDB element-names

  - 'mdb-title' :
    If 'mdb-title' is used in the xmltv-target element <title>, it will only be added if different from the existing xmltv title (see 2. above)
    If used in any of the other supported xmltv-target elements, there is no such restriction and it will be listed in any case.
  - 'mdb-starrating' 'mdb-description' 'mdb-plot' 'mdb-commentsummary' 'mdb-review' 'mdb-actor' 'mdb-director' 'mdb-showid' 'mdb-subtitle' 'mdb-episodeid' 'mdb-episodenum' 'mdb-showicon' and 'mdb-productiondate'

5. Attributes (might need completion)

  - for each of the xmltv-elements the following attribute can be specified
        (if not specified the existing one, if present in the xmltv, will be used) :
      - lang    for <title> and <desc> , default : no attribute
      - system    for <star-rating> , default : no attribute
      - type  for <review> , default: type="text"    ]]>

<!--mdb-starrating correction:

allows to convert the mdb-starrating into a value that suits a media-center starrating display. E.g. , the majority of the IMDb starrating values are between 4 (bad) and 8 (good) in a scale of 10. In a 5 star display system , like the one in MCE, there is too little difference between these values.
The following settings, first subtracts 4 from the grabbed mdb-starrating and multiplies the result by 1.2 with a maximum of 5 . That will convert the values above, in 0 (was 4) and 5 (was 8)
   Default values: subtract="0" multiply="1" and max="10"-->
  <mdb-starrating subtract="4" multiply="1.2" max="5" />

<!--The next two lines add mdb-title (if different) as an extra <title> element before the existing one:  -->
  <title lang="xx">'mdb-title'</title>
  <title>'title'</title>

<!--The following line replaces the existing <desc> by this one, composed as follows:
  The value of the first mdb-title, then ... [plot: , then the value of mdb-plot, then ] , then on a newline the existing description, then on a newline the text [imdb descriptin: , followed by the value of the mdb-description-->
  <desc>{'mdb-title'...}{[plot: 'mdb-plot']\n}'description'{\n[imdb description: 'mdb-description']}</desc>

<!--The next two lines replace the existing star-rating element(s) (if any) with the two specified here.  First is the existing followed by the mdb-starrating -->
  <star-rating>'starrating'</star-rating>
  <star-rating system="imdb">'mdb-starrating'</star-rating>

<!--It is also possible to add the two starrating values into one <star-rating> element:
  <star-rating system="mixed">From Site : 'starrating'\t\tFrom IMDb : 'mdb-starrating'</star-rating>  -->

<!--The next example shows that it is possible to create multiple elements, it splits the review data in two <review> ele-
```

```
ments-->
  <review>{Viewers comments : 'mdb-commentsummary'}</review>
  <review type="text">{IMDb review: 'mdb-review'}</review>

<!--channels, a way to exclude channels that don't need mdb processing.
  As default, all channels in the WebGrab++.config.xml will be used to select shows.
  Channels in the following list are excluded if update="" (left blank), any other value will keep the channel included.
  This list has the same format as the channel-list in WebGrab++.config and the channel files in the SiteIni.pack. -->
  <channel update="" site="disney.nl" site_id="DisneyChannel" xmltv_id="Disney Channel">Disney Channel</channel>
  <channel update="" site="tvgids.upc.nl" site_id="7K" xmltv_id="RTL 4">RTL 4</channel>
</settings>
```

rex.config.xml file :

```
<?xml version="1.0" encoding="utf-8"?>
<!-- Configuration file for the REX (Re-arrange and Edit Xmltv) postprocessor of WebGrab+Plus
by Jan van Straaten, July 2012
WebGrab+Plus Version V1.1.1
-->
<!--  Introduction:
  The purpose of this postprocessor is to re-arrange and edit the xmltv file created by the grabber section of WebGrab+Plus.
  This can be useful or necessary if the EPG viewer of the PVR/Media-Centre used, or the xmltv importer it uses, does not
support all the xmltv elements in the xmltv file created by WG++.
  It can:

  - Move the content of xmltv elements to other xmltv elements
  - Merge the content of several xmltv elements
  - Add comments/prefix/postfix text
  - Remove or create xmltv elements

  E.g.: If the PVR doesn't support import of credit elements (actors, directors etc.) it can add the content of them to the de-
scription and remove the original credit elements which are useless.
  Or , it can move the episode data to the beginning or end of the subtitle element
  Etc. ..

  Remark: This postprocessor is only fully effective if the xmltv input has a 'clean' xmltv structure in which the data is
properly allocated to the elements. If that is the case depends on the EPG source site and the design of the SiteIni file .
Some of the (e.g. customized) SiteIni files produce xmltv data that targets certain PVR/Media-Centre requirements already.
In these cases this postprocessor is less effective /useful.-->

<settings>

  <!--xmltv file : The xmltv target file in which the updated data will be merged with the grabbed EPG.
Because of the incremental nature of the grabbing process this file must be different (name and/or path) from the target file
of the grabbing as specified in WebGrab++.Config.xml <filename> !!
If omitted here or if by mistake the same file is specified, the file path will be changed to
C:\ProgramData\ServerCare\WebGrab\Rex\-->
  <filename>C:\ProgramData\ServerCare\WebGrab\Rex\guide.xml</filename>

<!-- Configuration of the elements:

1. Content and Values:
  This is best explained in a step by step fashion:
  Suppose you want to move the actors to the end of the desciption. You then specify:

  <desc>'description'\n'actor'</desc>

  The result is the existing 'description' , followed by, on a newline,  the actor(s) separated by the standard WG++ element
separator | .
  The result:
```

<desc>This is the original description.
Michael Douglas|Kim Basinger</desc>

You probably don't like the | as separator between the actors, so you specify anther separator like this:
<desc>'description'\n'actor(,)'</desc>
The result:
<desc>This is the original description.
Michael Douglas, Kim Basinger</desc>

You can make this prettier by adding some text to the actors addition:
<desc>'description'\nActors: 'actor(,)'.</desc>
The result:
<desc>This is the original description.
Actors: Michael Douglas, Kim Basinger.</desc>

A small problem: Suppose the source xmltv show doesn't have any actors, then the result would be not so pretty:
<desc>This is the original description.
Actors: .</desc>

To avoid that, the added text can be linked to the element it must be added to, like this:
<desc>'description'{\nActors: 'actor(,)'.}</desc>
Result with actors:
<desc>This is the original description.
Actors: Michael Douglas, Kim Basinger.</desc>

And without actors:
<desc>This is the original description.</desc>

An example with some more elements:
<desc>'description'{\n\tYear of production: 'productiondate'.}{\n\tProducer: 'producer(,)'.}{\n\tActors: 'actor(,)'.}</desc>
Result:
<desc>This is the original description.
Year of production: 2002.
Producer: Steven Spielberg.
Actors: Michael Douglas, Kim Basinger.</desc>

And another one:
<sub-title>{Episode: 'episode'\t}'subtitle'</sub-title>
Result:
<sub-title>Episode: 3.2/12.1 The original subtitle</sub-title>

You can also remove elements (but not the title!) from the xmltv listing by specifying an empty element, like this:
<actor></actor>
This will remove all <actor> elements
And this:
<credits></credits>
Will remove the <credits> element, including all its child elements like <actor> , <producer> etc.

Summary of Content/Values:

1. Syntax
- the content of the xmltv-target elements can be specified by means of a mixture of text and element-values.
- the element-values must be entered by their element-name enclosed by ''
- multiple value elements (like actor) will be converted to single value elements if the xmltv-target element is a single value element, like <desc>. The individual values will be listed with a (standard WG++ internal element separator) | as separator unless another separator is specified as follows:
'element-name(separator-string)' e.g. 'actor(,)'
- text and element-names can be linked together by enclosing them by {}. This will ensure that, when the element in it is empty, everything between the {} is ignored. E.g. {\nProduced in : ('productiondate')}

- the text in the xmltv-target elements may contain the following simple formatting :
  - \n or \r to force a newline
  - \t to add a tab

2. The allowed xmltv-target elements (the ones in the target file specified above) are :
  <title>
  <sub-title>
  <desc>
  <date> = the xmltv element name containing the productiondate
  <star-rating>
  <review> (=optional new xmltv element)
  <director> e.g to add /substitute the (additional?) mdb-director
  <actor> e.g to add /substitute the (additional?) mdb-actor

- IMPORTANT! : any of the above listed xmltv-target elements that is specified in this allocation specification, replaces the existing xmltv element and its content!

3. Supported element-names (from the existing xmltv listing, name definitions as in Appendix D) :
  - 'title' 'description' 'starrating' 'subtitle' 'productiondate' 'category' 'director' 'actor' 'presenter' 'writer' 'composer' 'producer' 'rating' 'episode' 'review' 'subtitles' 'premiere' 'previously-shown' 'aspect' 'quality'

4. Also supported are the additional elements created by the MDB-postprocessor.

- Important : This MDB-postprocessor automatically makes use of this REX-postprocessor. In that case the REX-postprocessor uses the allocation specification from the MDB config file mdb.config.xml and ignores the specification entered here.
  - 'mdb-title'

(if used in the xmltv-target element <title> it will only be added if different from the existing xmltv title, see for more details mdb.config.xml)
  - 'mdb-starrating' 'mdb-description' 'mdb-plot' 'mdb-commentsummary' 'mdb-review' 'mdb-actor' 'mdb-director' 'mdb-showid' 'mdb-subtitle' 'mdb-episodeid' 'mdb-episodenum' 'mdb-showicon' and 'mdb-productiondate'

5. Attributes (might need completion)
  - for each of the xmltv-elements the following attribute can be specified
      (if not specified, the existing one, if present in the xmltv, will be used) :
    - lang for <title> and <desc> , default : no attribute
    - system for <star-rating> , default : no attribute
    - type for <review> , default: type="text"]]> -->

<sub-title>{Episode: 'episode' }'subtitle'</sub-title>
  <desc>'description'{\n\t¤ Produced in: 'productiondate'. }{¤ Category: 'category(,)'. }{\n\t¤ Actors: 'actor(,)'}{\n\t¤ Director: 'director(,)'}{\n\t¤ Presenter: 'presenter(,)'}</desc>
  <credits></credits>
  <episode-num></episode-num>
  <date></date>
  <category></category>
  <review>{Ratings: 'rating(,)'.}</review>
  <rating></rating>
</settings>

APPENDIX D Example SiteIni files
